of thoracic phthisis. Indeed, I am not exaggerating I affirm that they are almost always practically ignored ether, even when the changes are of a pronounced kind, are of much consequence from a clinical point of view y remark in passing that no value whatever can be hed to certain phenomena supposed to be related to isis such as the presence of chloasma or undue ular irritability over the chest. A peculiar hypertrophy p or both mammary glands has been described, especially ales, due to a chronic mammitis, but I cannot remember ng noticed it in any of my cases The following are the tions of the chest walls to which I desire to draw cular attention as practical factors in relation to thoracic isis, in different cases and they are often more or less died.

The *superficial tissues* and *muscles* are usually more or wasted and this wasting may attain such a degree, even tients previously well covered, stout, or muscular, that ely anything but skin is left, all fat and even muscle ng practically disappeared The intercostal muscles are often much atrophied. Sometimes the muscles are more ed on the side of disease when it is unilateral. Surely portance of such a condition of things clinically is self nt, both in relation to symptoms and physical signs.

Another condition to be noted, of very common rence, is *abnormal rigidity* of the bony and cartilagi- framework of the chest, which may reach an extreme ee, so that the walls are practically immoveable. This tion is naturally most frequent and pronounced in elderly nts, and is often quite independent of the phthisis, but it no means uncommon in comparatively young subjects I believe may be definitely associated with a chronic sical process. In any case, when present, it is a change h always demands due recognition and an endeavour ld be made to estimate its degree and effects

Apart from an originally small and contracted, or so- d "phthinoid" or "alar" chest, the *changes in its shape capacity* produced by intra-thoracic morbid processes manifested externally in its walls, should also in my ion, be regarded as an important pathological factor in a of phthisis This region as a rule comes to present con able deviations from the normal as regards size and rmation, with marked irregularities on the two sides, the thorax may ultimately become practically a ned one These changes are naturally most pronounced ung and delicate subjects, whose ribs and cartilages are and yielding, but they also occur later and it is very rkable what a wreck an originally fine chest may ately become

In those cases where phthisis supervenes on previous *rmities of the chest,* these of course should always be n into account They may be of different kinds but are cially [illegible] nt when they have resulted from caries of spine [illegible] g to angular curvature and its associated itions, which cause serious embarrassment of the intra- acic structures at the best but when these structures are lved in phthisical changes, extensive it may be, the culties are proportionately increased.

The implication of the walls of the chest themselves *uberculous* lesions could hardly be overlooked and course they may be of considerable importance In ll instances they are obviously associated with the ks or cartilages Occasionally one meets with cases re there has been more or less extensive tuber ous disease of the absorbent glands in the super- al structures, some of which may still remain, while ers have caseated and suppurated, leaving behind un lthy scars, ulcers, or sinuses. Very rarely a kind of erculous infiltration of the tissues is met with, and in a ent case of rapidly progressive tuberculosis within the st with which I am acquainted, the mischief made its y externally through the walls and definite tuberculous nifestations were subsequently observed in connexion with soft structures

The rare condition—*subcutaneous emphysema*—must be ntioned as a possible complication in a case of thoracic thisis, in relation to the superficial tissues. It may not y follow mediastinal emphysema but has resulted very eptionally from the rupture of a pulmonary cavity into superficial tissues, as well as from perforation of a yngeal ulcer When present it can hardly be overlooked.

In this connexion it may be noticed also that morbid nges affecting the *diaphragm* may be associated with [illegible] phthisis which, though difficult to recognise or demonstrate during life, certainly in some cases contribute to the clinical phenomena, and it is well to bear in mind the possibility of their existence.

Variations in morbid conditions — The pathological changes which I have thus comprehensively sketched differ widely in their exact nature in individual cases of thoracic phthisis, as regards the structures actually involved, the extent and distribution of the mischief, the mode of progress of the lesions, and their combinations In some instances they are essentially destructive and progressive, especially when acute or subacute, and no attempt at arrest or repair appears to be made. Even in acute cases, however, the active changes may cease, things settling down into a chronic type of phthisis, or a practical cure may ultimately be effected In a large majority of cases the morbid processes are more gradual and slow in their advance, though progressive, while in others they remain unchanged for long periods, being often confined to a limited area, or reparative changes become a prominent feature, the fibroid element being then usually marked. While, as a rule, the thoracic conditions in phthisis are fairly simple and easily understood by anyone who has taken the trouble to study them and to gain a comprehensive knowledge of their possible nature, in not a few instances they become highly complicated, especially when the progress of the disease has been very chronic. The lungs themselves often present combinations of morbid changes sufficiently complex, from their character and extent; but when in addition, as is commonly the case, the other structures mentioned become more or less involved in different ways, whilst, it may be, independent but associated diseases affecting the chest are also present, the state of things is likely to be highly embarrassing, both from the pathological and clinical point of view. Moreover, some acute or accidental complication may at any time alter the complexion of a case very considerably and add to its difficulties.

With regard to the lungs, it may be stated generally that in the ordinary run of cases of phthisis different changes exist in different parts of the same organ, which are not only evident on post mortem examination but can be recognised during life. Thus it is usual to have one or more, it may be several, cavities in the upper part, with fibrotic changes not uncommonly, with further down areas of tuberculous and pneumonic consolidation undergoing caseation and softening, while the lower lobe exhibits miliary tubercles, scattered or in groups, which may be extensively distributed and are often firm or sclerosed Sooner or later both lungs are more or less involved, and the disease is more frequently bilateral at an early period, according to my experience, than is usually supposed. In very chronic cases both lungs may present remarkable appearances, associated with extensive or general pleuritic adhesions, of which I have here interesting specimens from cases which have occurred at University College Hospital within a recent period.

Pathological effects of phthisical and associated changes — Under this head it may be well to indicate briefly what are the chief practical effects of the various lesions met with in cases of thoracic phthisis, and they may be thus summarised —

1 Temporary interference with the action and functions of the respiratory organs, by consolidation and associated changes or by pleural effusion, which afterwards clear up. These may occur at an early period or during the course of a case and for the time being are often serious The heart may also be more or less disturbed in its action by such conditions.

2. Absolute destruction and consequent uselessness, either of a limited area or of extensive tracts, of the pulmonary tissues, thus permanently impairing in various degrees the respiratory function. Even when the phthisical process is arrested after cavities have formed, and fibrosis has taken place, the involved portion of the lung can be of no further service, though other parts of the organ may take on compensatory work.

3. The formation of morbid products of different kinds, often purulent and of a wasting or exhausting nature, and usually discharged as expectoration. Any kind of pleural effusion which has to be removed again and again, as well as empyema, also deserves mention under this head.

4 The formation and absorption of toxins or other deleterious products—associated with tubercle bacilli tubercle and its changes pneumonia, suppuration, &c. It

the well within a few hours of commencement of cesspool emptying. But there are other circumstances to be taken into account before a decision is arrived at. From the plan it will be seen that *the hole freshly made in the garden for the reception of cesspool contents was dug against a wall that runs toward and within three or four feet of the particular well, and that nearly midway between this hole and the well the suction pipe of pump No. II. passes immediately beneath the foundation of the wall on its way to the well.* It cannot be doubted that we have here special facilities for rapid passage of foul fluid from the recently removed cesspool contents to the particular well. Fluid matters poured against the wall would travel towards lower ground most readily and quickly along the foundation of this wall and could be thus led in the direction of the well; and, further, upon reaching a spot nearly midway between this starting-point and the well, such liquid matters could gain access to the trench in which the suction pipe of pump No. 2 had originally been laid, and following this new course alongside that pipe would be conducted directly into the well. Whether or not the above was the course actually taken by foul liquid matters soaking from the cesspool deposit hole to the well cannot now be determined. Mr. Freeman sought to put this surmise also to the test, but he failed for the reason that the plumber who had meanwhile been employed in laying on the Norwood Water Company's supply to the terrace had removed the suction pipes of the wells. In removing the suction-pipe of pump No. 2 the interval of ground between the cesspool deposit-hole and the well had become so greatly disturbed that trustworthy evidence on the above point was not to be had."

In 1883 Mr. W. H. Power (now the chief medical officer of the Local Government Board) made an important report on an outbreak at Hitchin on which Dr. Buchanan makes the following remarks in his report as chief medical officer: "In a report by Mr. Power on an epidemic prevalence of enteric fever at Hitchin fresh illustration is given of the now well-known fact that the distribution of enteric fever often follows, both in place and time, the distribution of impure water in such a way that the water cannot but be regarded as conveying the infection of the fever. The particular interest of the Hitchin outbreak arises from the circumstances that it was the water-supply of the sanitary authority which had become thus infected and that the impurity, certainly connected (as Mr. Power's report shows) with the fever, yet had not been recognised as the cause of the fever until his inquiry. In these respects and knowing the ability of cholera to be conveyed by water in the same manner as enteric fever, the case of Hitchin is of particular value to the present report." Mr. Power's description is as follows:—The public water-supply of Hitchin having come thus under suspicion, the facts already recorded as showing various risks to the water on its passage to the service reservoir appeared of graver import, and now an additional and exceptional risk to the water, not as yet defined, demanded especial consideration. This further opportunity for pollution of the public water-supply consisted in the circumstances that at the pumping station an eight-inch overflow pipe, contrived to convey surplus water from the receiving tank and pumping well into the river Hiz, permitted on occasion reflux of the river water into the tank. Discovery of this defect in January last was not only startling but was in a way satisfactory to the sanitary authority, for it went far to explain a difficulty that had for some time troubled persons concerned with the waterworks—viz., that without obvious cause, suddenly and at uncertain intervals, the water in the pumping well had been apt to become turbid. Along with identification of the cause of this occasional turbidity of the water service came recognition also that coincidence of two separate conditions was requisite for back flow of the river into the tank. These were slight rise in the level of the water in the river and a reduction by pumping operations of the level of the water in the tank and pumping-well to the extent of arresting overflow to the river from the tank through the overflow pipe. How often in times past these conditions have been coincident it is impossible to say, since the occasions of turbidity of the water-supply have not been recorded. But in the winter just passed, under circumstances of admittedly exceptional liability of the river to flood, and with modification last November of the routine of the engine-man's labours bringing about a doubling on pumping days of the hours of pumping, opportunities for coincidence of the conditions requisite for pollution of the pumping-well have seemingly been more frequent, and unquestionably during this winter turbidity of the water in the pumping-well has occurred on several occasions. The defect of the overflow pipe here noted was, it should be stated, rectified on Jan. 13th, since which no further turbidity of the water-supply has been observed. It would perhaps be difficult to over-estimate the gravity of the above defect in the water service apparatus. For the Hiz, which in its course throug the town is hardly more than a ditch a few feet in widt receives refuse matter cast into it from poorer dwellings abutting on it, and the river water, therefore, is liable contain some of the most dangerous qualities of sewage. O one occasion of cursory inspection of the river I mysel observed littered on the edge of the stream, just above th point of entrance to it of the overflow pipe from the wat works and ready to be carried there by the first rise in le of the river, diarrhœal excrements cast out from the ba windows of dwellings on its banks. It would seem, ther fore, that given the existence of enteric fever in Hitchin a the not rare chance of excrement from fever patients gettin into the river, with the liability of the river water to occasion supplement the public water-supply, there shou be no difficulty, if the water service has really been i fault, in getting some more precise explanation of th epidemic diffusion of the fever in the town than h yet been afforded. Accordingly I sought to ascertai whether or not—having regard to a two weeks' int (or thereabouts) such as usually elapses with enteric fe between the occasion of infection of an individual an the first beginning of his illness—there had been any observe occasions of turbidity of the public water-supply that cou have been related to outbursts of fever in the There was, however, difficulty in ascertaining this, for, has been mentioned, no record has been kept at Hitchin the occasions of turbidity of the water service. In the en was able to fix the date of one only of such occasion arriving at it in the following fashion. The outburst fever in mid-January, which was most recent, and the fac about it most likely therefore to be remembered, was ta as a test case, so to speak, of ability of the water service spread fever, and information was sought as to turbidity the town water two weeks previously—viz., about the end December—with the following result. On the afternoon Saturday, Dec. 30th, a day on which a heavy rainfall 0·67 inches was registered in Hitchin, very general complai had, it turned out, been made to the waterworks man that the water delivered by the public mains was thick turbid; and examination forthwith undertaken by the wat works people revealed the fact that the water in the pumping well and in the service reservoir also was in like conditio Seemingly, it was the amount on this occasion of turbidi and its close sequence on the rainstorm that raised among people concerned about the waterworks suspicion as to origin and which led eventually to detection of the offe ing overflow pipe. Now, so far as I could learn, water in the Hiz on Dec. 30th, rose suddenly rapidly, and it could at once have passed back, and in siderable volume, through the overflow pipe into the ing-well, for in view of the storage of water necessary f Sunday's consumption pumping operations had by 4 P.M. Saturday lasted nine hours, thus reducing to a comparativel low level the 'spring water' in the pumping-well, an leaving the pipe intended to conduct surplus water from th pumping-well into the river to serve as a conduit for bac flow of river water into the pumping-well. In the face the above evidence it is impossible not to admit that in probability there has been direct relation between the ci cumstances of pollution on Dec. 30th of the public wat service and the outburst of fever in mid-January. As the outburst in mid-December, however, like causation not, in the absence of like positive evidence, be quite confidently affirmed. But looking to the very simila behaviour of the two outbursts, and to the other evi that has been adduced tending to convict the water servic as responsible for the observed distribution of the fever, i is easy to credit for this, the first outbreak, similar dir relation to the public water service. And in this connexio may be noted some facts or coincidences that are interestin though not perhaps worthy to be classed as evidence. regard to both outbursts there were matters connected wi the water supply that, on a hypothesis of water causatio might have been concerned on each occas [illegible] the oth wise unexplained rapid declination and [illegible] ruary, ou of the outburst. As regards the second [illegible] burst, discovery of the defaulting overflow pipe and in mid-January of this source of pollution of the public water service was followed some two weeks later by sudden cessation of the fever, and similarly complete emptying and thorough cleansing on Dec. 14th of the storage or service reservoir (which, for the purpose of the present hypothesis, may be regarded as having been the storage reservoir of fever material also) was followed again in about two weeks by well-nigh complete disappearance of all fever that can be considered as related to any common cause of the December outburst."

In 1889 Dr. J. Ashburton Thompson, chief medical inspector of the Board of Health of New South Wales, issued a report on an outbreak of typhoid fever at Balranald which he traced to pollution of water in a certain tank which was supplied with rain-water and was sunk in the marly clay and not known to be puddled outside; near it were several cesspits. It was shown that 14 households, in all 124 persons, were supplied with this water, and an analysis of the cases in those 14 households in which that water was regularly drunk, in comparison with that of households the people of which are not known to have drunk it, gave the result that of 124 persons who regularly drank the water 34 per cent. suffered; while of 476 persons whose relation to the water cannot be defined (that is, who were not known to have drunk it) only 5·2 per cent. suffered.

I am indebted to my friend Professor Brouardel, for many years Doyen of the Faculty of Medicine of Paris, for the particulars of three outbreaks of typhoid fever which he investigated and reported on in 1887. The first occurred at Pierrefonds. In August and September, 1886, 24 persons from Paris and Versailles went to live in three adjoining houses at Pierrefonds; 20 of these persons contracted typhoid fever more or less severely, and four of them died. It was ascertained that cases of enteric fever had occurred in these houses before, one of them having been visited five times by this fever between 1874 and 1883. The water-supply in the houses on both sides of the street was from wells which communicated with one another through the very porous soil. This was proved by the fact that a few years before a fruiterer who kept one of the houses on the other side of the street let fall a can of oil into his well, and three or four days afterwards the oil appeared in the well of one of the houses in question. The subsoil water supplying these wells passed either alongside of, or below, the cesspools of the different houses. These cesspools were not watertight, being constructed of small stones without any cement. One of them, with which two of the infected houses were connected, had a small drain from its lower part discharging into the neighbouring stream. This drain at the time of inspection was blocked, the cesspool had not been emptied for 30 years, and it was almost full of hard deposit which had to be removed with a spade. The wells for the two houses were dug at distances of 9 and 20 metres respectively from this cesspool and in such a position that the level of the bottom of the cesspool was a little above that of the surface of the water in the wells. To increase the danger the rain-water from the roofs was also discharged into the cesspool, so that whenever there was a heavy shower the water washed the fæcal matters into the subsoil and thence into the wells. A specially interesting observation was made with regard to the dates of attack. In one house five persons out of seven were attacked, all on August 27th or 28th. In another seven persons out of nine were attacked between Sept. 17th and 22nd except one domestic who was attacked on Sept. 10th, whereas in the third house all the members of the family were attacked between Sept. 25th and 28th, so that each family was attacked at a different time, but all the members of one family were attacked at about the same time. Dr. Brouardel points out an interesting explanation of this in the fact that there were heavy rains on August 2nd, 22nd, 23rd, and 24th, and Sept. 3rd, and that the attacks at these three houses were in each case about from 20 to 25 days after these rains. He also adds that the difference in the distance of the wells from the cesspools no doubt had some relation with the difference of the dates of the attacks. Samples of water from these wells were bacteriologically examined by Dr. Chantemesse, the director of the Bacteriological Laboratory at the Faculty of Medicine of Paris, and by M. Widal, and they obtained from one of them (a month after the outbreak of the disease) cultivations of the Eberth-Gaffky bacillus which they identified by comparison with cultivations obtained from the blood of the spleen of a person suffering from typhoid fever. The water was also chemically examined but it was found that the organic matters in solution in it had been almost completely oxidised. Of this Dr. Brouardel remarks: "This is an observation of which the importance is easily understood in the discussion of the question of the purification by the soil of sewage water charged with excremental matters. It shows that the soil destroys organic matters which come in contact with it; they undergo nitrification in it; but it is not the same for the germs of typhoid fever. They persist a long time in the earth; they lived for more than a month in the water of one of the wells of Pierrefonds." He then goes on to show that a case of enteric fever had been imported from Paris into one of those houses at Pierrefonds at a remote period. As is very usual in such cases the intensity of the disease varied very much among the persons attacked. Of this Dr. Brouardel says: "Of 24 persons 20 were attacked. Of these four died; six recovered after a well-characterised attack of typhoid fever; six others suffered from *états fébriles typhiques*; two others from short attacks called *embarras gastriques*, apparently not specific; and two had violent attacks of fever. The character of these different manifestations only obtains its true significance because they were simultaneously developed among the same surroundings." "If these morbid conditions had not burst out in the same focus their nosologic value would certainly have been misunderstood." On this point he quotes P. Lorain, "De la Température du Corps Humain et de ses Variations dans les Divers Maladies." "Perhaps there is a *typhoidette* as there is a *varioloid*. There is no reason why one should not admit this hypothesis, but it is a hypothesis." Of this Dr. Brouardel says: "That which Lorain considered as a hypothesis seems to me to-day absolutely proved, and I demand that one should admit in nosology this name of *typhoidette* which has the great advantage of recalling, more than the names actually used, the source from which some of these gastro-intestinal conditions originate." Dr Brouardel then attacks the interesting question of immunity and asks whether these mild forms of the fever infection afford a relative immunity from a fresh attack of the disease. "Does the *typhoidette* differ from typhoid fever as the varioloid does from variola?" He considers that it does so and that it is to this cause that we must assign the relative immunity which the inhabitants of countries often visited by typhoid fever enjoy, and I may add here that this very fact has been observed among the Boers during the present war.

The second outbreak, which took place at Clermont-Ferrand, prevailed from September to December, 1886, and was investigated by Dr Brouardel and Dr. Chantemesse. This outbreak was "more severe and more generally spread in the southern portion of the town which includes the best quarters." There were two separate outbreaks, not only at Clermont-Ferrand but at Mont-Ferrand, towns two kilometres apart. These outbreaks "had the same course in the two towns and their maximum height was almost on the same days." On the other hand, the outbreak did not attack Royat and Chamalières, two little towns equally near to Clermont-Ferrand, yet the explanation was found in the fact that Clermont-Ferrand and Mont-Ferrand are supplied with the same water, while Royat and Chamalières have each a separate and independent source of supply. It was observed that the persons in the two infected towns who drank only boiled water or mineral water were not attacked, and that in a convent at Clermont Ferrand, supplied by a special fountain in its park there was only one case of typhoid fever and that occurred in the case of a person who had visited her parents and had drunk of the town water-supply. The first outbreak appears to have been caused as follows. In August a woman suffering from typhoid fever lodged in a villa at 35 metres from the water conduit; the cesspool of the house was not watertight and there was a washhouse which discharged its water into a stream passing over the water conduit, but the landlord stated that the visitors' washing was done in the public laundry at Royat, close to which was a water conduit for Clermont-Ferrand, the pipes of which were "made of earthenware in such bad condition that eight days after our inspection at the end of December the municipality of Clermont has thoroughly replaced the earthenware pipes by iron ones." 20 days afterwards typhoid fever broke out in the town, appearing in nearly all quarters at once. The second outbreak, on the other hand, appears to have been caused by the excretal matters of two typhoid fever patients having been thrown out in the street in the month of October "on this soil of lava cracked with fissures of 20 to 25 metres in depth either at the point where the water of Clermont is obtained or close to it." The second outbreak took place at Clermont-Ferrand and at Mont-Ferrand at the beginning of November and especially towards the middle of the month. The typhoid bacillus was found in the water in the cistern of a house where there had been typhoid fever during the second outbreak. This cistern had not been cleaned for two years and a young girl who drank water from it had an attack of typhoid fever.

The third report, kindly forwarded me by Dr. Brouardel, was on an investigation made by himself and Dr. Chantemesse in 1887 into some outbreaks of the disease in the barracks of the Marines at Lorient. They reported that while the fever raged among the troops the civil population remained almost intact, while during the cholera epidemic in 1866 the population was attacked and the soldiers almost all escaped. It appears that the inhabitants of Lorient and the troops drank water coming from two different places. The causes of the outbreak were stated to be as follows: "The principal cause is the intermittent infection of the drinking-water; the secondary cause is defective installation of the latrines in the barracks. It appears that the excremental matters of the town are collected in moveable pails in which they are carried outside the town and spread upon the fields as manure twice a year, in the beginning of February and during August. This is regularly done by the farmer of the fields, under the surface of which the waters which supply the arsenal collect. The springs under these fields are produced by the rain-water which falls on the neighbouring hills and in the valley above the fields. Sometimes the level of the underground water which forms the spring is only separated from the surface of the soil by a bed of pebbles of a few centimetres in thickness. These waters, which at their point of collection are already polluted, arrive at the arsenal in old pipes which are not watertight. The principal conduit traverses the subsoil of heavily manured meadows and of the garden of the hospital on which the excreta of all the patients are constantly being thrown. In the passage of this conduit across that garden the conditions are such that it is not possible that the drinking-water should not be sometimes polluted. The secondary cause of propagation of the fever is the infection of the air due to the installation of latrines which are mere wooden tubs placed immediately under the windows of the barrack-rooms. As soon as these latrines are infected by typhoid excreta they can spread around the germs of the disease. On the first and second floor of the barracks one window is more particularly situated immediately above the tubs; the three beds placed by the side of this window on the first and second floors have been occupied by soldiers who have all been attacked with typhoid fever. Around them in the same messes of the barracks the victims of the disease were much more widely separated. Thus twice a year human excrement is thrown upon the meadows where the source of water which supplies the barracks of the arsenal springs and twice a year an epidemic of typhoid fever bursts forth. The manuring takes place first in January and February and then in August; the epidemics appear in March and in October or November. The rain is the bond which closely unites these two facts, the manuring of the land and the explosion of typhoid fever." Further proof, if any were necessary, is to be found in the fact that "for some time past in order that the recruits may avoid the dangers of living in the barracks of the arsenal they have been made to encamp on their arrival at the 'Polygone de Lorient' supplied by the town water. While typhoid fever has raged in the arsenal at its ordinary periods there has not been a single case of it among the recruits."

Among instances of the pollution of the water of deep wells are the following. In 1879 (ninth report of the medical officer of the Local Government Board) is a report by Dr. Thorne Thorne of an outbreak of enteric fever at Caterham and Redhill which Dr. Buchanan summarised as follows: "(*b*) Dr. Thorne's investigation of a strongly-marked outbreak of enteric fever at Caterham and Redhill resulted in conclusive proof of the manner of its distribution and was of singular interest as demonstrating how limited a quantity of infective material may suffice under favouring circumstances to do wide-spread mischief. In one of the wells of the local water company a new adit was being formed and among the workmen was one who during his occupation in the adit suffered from a slight attack, at the time unrecognised, of enteric fever. He, when pressed by diarrhœa, used for his relief a bucket that was provided for raising to the surface the chalk dug from his workplace underground. It was found to be certain that the well-water could thus have become contaminated and there was no suggested way of its contamination by any other means. For the rest, quite satisfactory evidence connected the supply of water from this well with the prevailing epidemic that extended beyond Caterham to Redhill and other localities supplied by the company's water."

In 1889 Dr. Gresswell reported on the prevalence of typhoid fever at Cradley (Worcestershire). He traced the disease to water from a particular well in the sandstone, near which there was an old brick and mortar culvert receiving drainage of houses, while only 20 yards from the further end of a heading in the well and on ground rising somewhat steeply therefrom there was the churchyard. He showed that the defective culvert had received enteric fever discharges and that no doubt by leakage from it the well became infected. (Nineteenth report of the medical officer of the Local Government Board.)

In 1889 Dr. David Page reported on an outbreak of typhoid fever at Houghton-le-Spring (Durham), the cause of which is of exceptional interest. He traced the epidemic to the water of a well or staple sunk to a depth of 330 feet into sandstone strata of the coal measures, and the investigation is of such importance that I quote at length from the end of the report: "In looking around beyond the immediate vicinity of the well for possible opportunities of contamination I had visited early in my inquiry the farmhouse of Herrington Hill. This is situated about three-quarters of a mile to the south of Herrington Colliery on rising ground and about 150 feet above the level of the surface of the well. The farmhouse and buildings are upon the magnesian limestone, the beds of which dip towards the north. Owing to subsidences caused by the colliery workings below fissures extending to the surface exist in this locality. The drainage of the farm buildings, of a cottage, and of the farmhouse itself (in which latter there is a water-closet) is conveyed to a tank. The overflow from this tank escapes and disappears down an adjoining fissure in the ground. To determine whether a connexion existed between this fissure (three-quarters of a mile from the well) at Herrington Hill farm and the water-bearing strata supplying the 'staple' I suggested that common salt should be dissolved and thrown down the fissure. Instructions were given to this effect and two tons of salt were accordingly thrown down on May 11th. At this date the discovery of the 'feeder' in the 'staple' had not been made and testing of the water as pumped from the well did not give any conclusive indication of increase of chlorides. On the discovery of the 'feeder' a week later a clue to the excess of chlorides shown by it (as compared with the body of water in the well) was apparently furnished and, as will presently appear, the source of the chlorides was in the end conclusively demonstrated. From May 24th a series of daily testings of the relative amounts of chlorine in the water of the reservoir and of the 'feeder' were made. The chlorine in the water of the reservoir varied from 2·3 to 2·8 grains per gallon. On May 29th, with a view of placing beyond doubt whether the increase of chlorine thus shown was due to the salt thrown down the crevice at Herrington Hill, five tons of salt were washed down the crevice with a hose-pipe running for twelve hours, during which time it was estimated that some 100 tons of water were discharged. On the following day the chlorine present in the water of the 'feeder' rose to 15 grains per gallon. The testing was continued for a few days longer and on June 5th the chlorine reached the maximum amount of 24 grains per gallon. During the next few days it fell again to the former amount. The connexion between the two localities, the farm tank and the 'staple,' was thus conclusively established and the source of excremental contamination of the water-supply demonstrated. Specific contamination of the sewage from the farmhouse could not, however, be made out, no illness of a character resembling enteric fever having been known to occur at the farm during recent years. It remains to add that since the discovery of the 'feeder' arrangements had been made by Mr. Lishman for the supply to the affected district of water for drinking purposes from wholesome sources. Warnings had been issued to the people against resorting to the tap-water for drinking purposes and it was further decided to abandon the Herrington water as a source for domestic supply. To meet the immediate exigencies of the case and to guard against danger from a continued distribution of this water the Houghton service was turned on and distributed through the Herrington mains for two hours night and morning. But as this supply was insufficient to meet the requirements of the whole of the district arrangements were made and actually carried out for boiling the supply pumped from the Herrington well before it entered the reservoir. Engine boilers, which were fortunately at hand, were erected and adapted to this purpose, and on June 2nd these arrangements were completed and in operation On the occasion of my final visit to the district on June 7th I witnessed the remarkable and unique instance of the delivery to the mains of a water-supply which had been actually submitted to a boiling temperature " To fill the water mains of a town with water which had been all boiled was indeed a remarkable and unique experience.

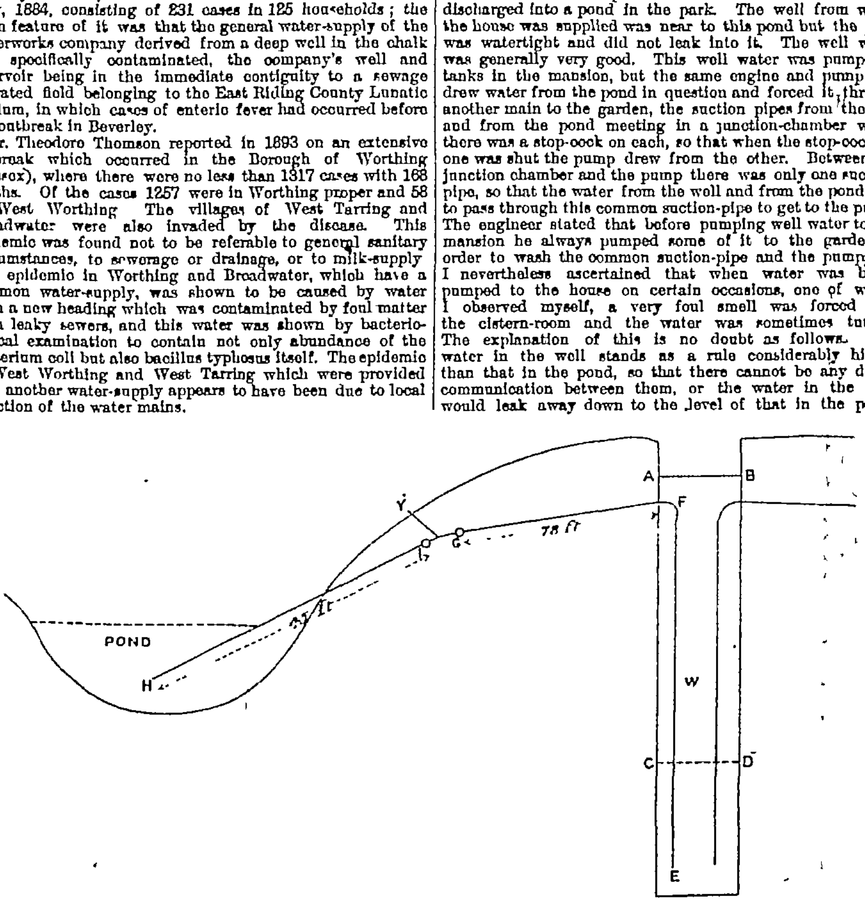
Beverley (Yorkshire)—Water-supply chiefly from borings into chalk which are occasionally found to be polluted by defective drains in their neighbourhood (there were 165 houses supplied by a private waterworks company); other sanitary defects; an outbreak of enteric fever occurred in July, 1884, consisting of 231 cases in 125 households; the main feature of it was that the general water-supply of the waterworks company derived from a deep well in the chalk was specifically contaminated, the company's well and reservoir being in the immediate contiguity to a sewage irrigated field belonging to the East Riding County Lunatic Asylum, in which cases of enteric fever had occurred before the outbreak in Beverley.

Dr. Theodore Thomson reported in 1893 on an extensive outbreak which occurred in the Borough of Worthing (Sussex), where there were no less than 1317 cases with 168 deaths. Of the cases 1257 were in Worthing proper and 58 in West Worthing The villages of West Tarring and Broadwater were also invaded by the disease. This epidemic was found not to be referable to general sanitary circumstances, to sewerage or drainage, or to milk-supply The epidemic in Worthing and Broadwater, which have a common water-supply, was shown to be caused by water from a new heading which was contaminated by foul matter from leaky sewers, and this water was shown by bacteriological examination to contain not only abundance of the bacterium coli but also bacillus typhosus itself. The epidemic in West Worthing and West Tarring which were provided with another water-supply appears to have been due to local infection of the water mains.

In 1894 Dr. Thomson also reported on simultaneous outbreaks of typhoid fever and of fever of less definite sort at various places in the Borough of Newport, Isle of Wight. He found that these outbreaks were referable to a public water-supply common to all the invaded places. This water-supply was derived from a well in the chalk at Carisbrook and was found to be open to dangerous contamination from the leaky drains of houses near the waterworks and standing on the chalk, and also from a filthy mill-pond. There was, moreover, serious risk of dangerous pollution of the water in the deeper strata of the chalk supplying the wells, from the existence of numerous cesspools within the area drawn upon by the two wells.

In 1895 Dr. Bruce Low reported on an epidemic of typhoid fever at Raunds (Northamptonshire). There were two distinct groups of cases, each group being "associated with use of water from a different public well that had become specifically polluted The closing of these two wells, one after the other, was followed by a marked subsidence of the outbreak."

A most interesting and remarkable case of the pollution of a deep well water has come under my notice recently. In a large country house where there had been a case of typhoid fever I found that the main sewer leaked badly into the land drains of the park. A number of these land drains discharged into a pond in the park. The well from which the house was supplied was near to this pond but the pond was watertight and did not leak into it. The well water was generally very good. This well water was pumped to tanks in the mansion, but the same engine and pump also drew water from the pond in question and forced it through another main to the garden, the suction pipes from the well and from the pond meeting in a junction-chamber where there was a stop-cock on each, so that when the stop-cock on one was shut the pump drew from the other. Between the junction chamber and the pump there was only one suction-pipe, so that the water from the well and from the pond had to pass through this common suction-pipe to get to the pump The engineer stated that before pumping well water to the mansion he always pumped some of it to the garden in order to wash the common suction-pipe and the pump, but I nevertheless ascertained that when water was being pumped to the house on certain occasions, one of which I observed myself, a very foul smell was forced into the cistern-room and the water was sometimes turbid The explanation of this is no doubt as follows. The water in the well stands as a rule considerably higher than that in the pond, so that there cannot be any direct communication between them, or the water in the well would leak away down to the level of that in the pond, which is not the case. When, however, the level of the well water has been considerably reduced by pumping, as is frequently the case, if it so happens that both of the stop-cocks are left open, the two suction-pipes must act as a siphon and the water from the pond be sucked over into the well, and there can be no doubt that the water in the well



When the water level in the well W is at A, B, if the valves G and I are open water runs from the well by pipe E, F, H into the pond, but if the water level is lower than that in the pond, as at C, D, and both valves are left open, the suction pipe and pump Y being sound, the water in the pond would be siphoned into the well has not been infrequently contaminated in this way. (See Diagram.)

Dr. Pistor of Berlin has kindly forwarded me two reports on polluted well waters. One, that of Dr. Mewius of Cosel (Silesia), on an outbreak of typhoid fever which occurred in that town in October, 1899, and was traced to the use of polluted water from the well of one of the hotels in the town[2]; and the other by Dr. Bloch of Beuthen (Silesia) on a serious outbreak of the same disease which took place in that town from June to October, 1897, and was traced to the pollution of the town supply by excremental matters from the mines which filtered through the soil into the wells of the public water-supply after a heavy flood which swamped the mines and washed the fæcal matters out of the pails in the mines before they could be removed.[3]

My friend Professor Kuborn, M.D., of Seraing, Liège, the President of the Royal Society of Public Health of Belgium, has kindly forwarded me a number of reports to the Minister of Agriculture by the provincial medical commissions of that country, from which I find that the spread of typhoid fever there is due (Report for 1891) "for many places to the pollution of the water-supplies, for some to importation and to direct contagion; in these the relations of cause and effect are precise. Lastly, in a more vague sort of manner overcrowding, moisture, and want of cleanliness are alleged causes." That it is due to polluted well-water is not to be surprised at considering that the following is given as a description of the wells supplying the working classes in one of the great towns: "A well surrounded with privies, heaps of manure, and goat-stables furnishes water to all the inhabitants. These come there to obtain the water with vessels which have served for all sorts of purposes. Most of the inhabitants are workpeople employed in the city—a fact which explains the rapid spread of the disease." In another report we are informed that while the water is at fault in some places in others "it is the houses which are at fault, whether by overcrowding or by filth."

In Luxembourg I find from the report of works carried out during 1892 an account of an outbreak at Marcour, "which has for the last 15 years had a public water-supply and which during that time has not been visited by typhoid fever, but the water-supply to the inhabitants was completely spoilt on account of the drought which had laid dry the open end of one of the main pipes drawing water from a stream; various animals having found their way into this pipe died there and the decomposition of their bodies polluted the whole of the water-supply. As soon as this cause of pollution was withdrawn a stop was put to the epidemic. And in another place called Bastogne, where there had not been a single case of fever since 1887, when the public water-supply was established, "the drought having diminished the quantity of water available, the communal authority allowed resort to be made to old wells, recommending the people by placards not to use the water for drinking. But a certain number of the inhabitants took no notice of this warning; 20 days after the reopening of the wells there were 30 cases of typhoid fever; a month later 100 cases, of whom 10 died."

Again, in the report for 1893 we are told that "in the great majority of cases it has been possible to trace the origin of the disease and the causes of the same, which were found almost always indicated. The most frequent by far consists in the pollution of the drinking water due to the defective construction of wells, the filtration of organic matters through their walls, the mixture of spring or river waters with waste waters in a state of putrefaction, of manure deposited on the fields or in the proximity of houses, especially after heavy rains have washed the country, cleansed the streets, and made the cesspits and the water-courses overflow. Next to this came the importation of the disease by individuals, most frequently workmen coming home from an infected locality; direct contagion operating habitually between persons of the same family or living together in small apartments; emanations from foul sewers; and the want of disinfection of the stools of typhoid patients." In the report for 1900 I find it stated that "sometimes typhoid fever is also spread by means of the bad habit which farmers have of throwing typhoid excreta on the dung-heaps. It has resulted that in the spring while spreading the manure on the fields the workmen who had carted the winter manure were infected by the bacilli which had been deposited in the autumn. The manure in preserving its temperature, its humidity, and also certain salts and albuminoids, supplies them with an excellent cultivating medium."

Water-supplies have sometimes been shown to be polluted at or near their springs by infiltration into them of excremental matter, and outbreaks of typhoid fever have taken place when such matter is specifically polluted. Among these are the following.

Bricksworth (Northamptonshire).—Dr. Thorne in 1874 reported that this fever was habitually prevalent and that the water was liable to surface and excremental pollution.

Dr. Hubert Airy reported on an outbreak of enteric fever at Blackburn in Lancashire in 1881 as follows: "This water-supply of Blackburn runs the risk of pollution at its several sources. There is risk at the gathering ground above Pickup Bank; there is risk at the White Birk colliery of some accident similar to that which befell the Caterham well; and there is risk at the well on Revidge, for houses are pretty numerous round about and the soil is a porous sandstone rock. Moreover, as regards the water from Pickup Bank there is risk at very many points along the route by which it is conveyed to the town. The stone culvert ...... is of rough construction, built of the ragstone of the district in rude wedge-shaped lumps, fitted together without mortar or cement, but well bedded in thick puddle; and remembering that this culvert has lain for more than 30 years, only three or four feet deep, on the slope of the hillside, with a constant tendency to increase of pressure on the upper side, and lessening of pressure on the lower side, it can hardly be supposed that the structure is still sound throughout. Indeed, on one or two occasions at different points the crown of the arch has fallen in, and probably at a hundred points it has yielded more or less, so as to admit a leakage of sub-surface water on the upper side." After pointing out that there is danger from the manuring of the ground over the culvert he goes on to say: "There is also the sewage and ordure of Belthorn, the village on the crest of the hill, above the line of the culvert, to be taken into account. At the time of construction of the waterworks Belthorn had no sewer or cesspool, but disposed of its slops and excreta close around the dwellings. Of late years the house-slops have been received in a roadside sewer delivering into a watercourse which formerly was impounded in a little 'lodge' close above the culvert and used to supplement the supply from Pickup Bank. Even to the time of my visit the conduit remained open at this point, but the lodge had long before been emptied by a pipe carried under the culvert. Still, it has occasionally happened that this pipe has been choked with rubbish or with snow and the water has half-filled the lodge before it has been possible to clear the pipe again. 'The water bailiffs, however, declare that the water in the lodge under these circumstances never reached the open conduit. Again, there are one or two other points *where sewage from Belthorn has to pass over or under the culvert* and where the accident of a defective joint might admit impure water to the latter. The drainage from one row of houses goes into a cesspool on the hill slope. The cesspool sometimes overflows and the liquid runs down a lane and enters a drain which passes under the culvert. Even in the last 20 yards of its course before it discharges into the Guide reservoir the culvert is in manifest danger of receiving soakage from the neighbourhood of a row of cottages (Shorrock's-row) in the village of Guide."

After describing how he found a place where water was leaking into the culvert he continues: "On opening the ground at a corresponding point in the pasture above the men struck upon an old stone land drain which was then traced some distance back and appeared to run obliquely across the meadow from the upper side. Approaching the culvert it ran within nine yards of the last of a row of privy pits which lay outside the bounding wall of the back yards of Shorrock's-row, accessible from the meadow, for the convenience of the farmer who took the manure. The farmer assured me that he spread this manure only on the land below the culvert, never above, but there were signs of the overflow from the privy pits having been conducted on to the pasture above the culvert. The impression left upon my mind, though I could not positively prove the fact, was that there was a probability of soakage from these privy pits and from the slop gutter in front of Shorrock's-row affecting the purity of the water in the culvert. I have dwelt somewhat at length on these dangerous conditions along the line of the conduit because I shall have to show that the chief outbreak of enteric fever in Blackburn followed close upon, and possibly was caused by, the occurrence of enteric fever at Belthorn and Shorrock's-row. The water on leaving the culvert, just within the wall of the reservoir enclosure, runs in an open enclosure for 20 or 30 yards before discharging into the reservoir. An empty can or two lying in this channel showed that it was exposed to casual additions and I noticed just within the gate of the enclosure and immediately over the mouth of the culvert the remains of human ordure. In the side of the open channel is a gate-sluice which, when desired, can be set open so as to divert the stream, or part of it, into an open by-channel which runs down between the Guide embankment and the public road and is finally turned into the lower (Fishmoor) reservoir. In its course it receives the contents of a ditch which, when traced back, *is found to take origin* at the back of some dwellings in the upper part of Guide village, whence it comes along a cartway trodden and befouled by cattle, past a farmyard, and through a field, exposed in its whole length to the risk of pollution. I heard tales also of mischievous fellows throwing 'nast' (filth) into the reservoirs themselves. The six-foot enclosure wall is easily climbed."

[2] Zeitschrift für Meidzinalbeamte, Heft 19, 1901.

[3] Deutsche Vierteljahrschrift, 1898.

Dr. Airy then shows how one of the privies had been shortly before the outbreak infected by the stools of a man, Aspden, who had typhoid fever and goes on to say: "This case was not visited by the medical officer of health nor by the inspector of nuisances; the danger to the public health *attending the presence of a case of enteric fever so near the main artery of the water-supply was overlooked.* An unskilled labourer who works under the nuisance inspector was sent to the house with some carbolic acid powder. Aspden states that this disinfectant was used to discharges which were then thrown into the privy, one of the row of privies that have their pits opening to the meadow through which the water-culvert passes. Slops and rinsings of vessels undisinfected were thrown down a sink in the backyard or thrown into the roadside gutter in front of the house. Either channel would carry them, as already described, immediately over the water-culvert, at points where it was evident on internal examination that fluid was in the habit of oozing into the culvert. Any such admixture, supposing it to occur, would be infinitesimal in comparison with the quantity of water flowing in the culvert, and that again, in comparison with the whole body of water in the reservoir which received it, would be but as a river flowing into the sea. It certainly taxes the imagination to suppose that so minute a portion of infected matter would suffice to give a poisonous taint to so large a body of water, unless it possessed the property of self-multiplication." (Eleventh report of the medical officer of the Local Government Board, 1881.)

At Rotherham (Yorkshire) and two adjoining districts typhoid fever and "fever of a less definite sort" was again prevalent in 1891–92, and Dr. Theodore Thomson reported that it was "not due to sewerage or drainage, nor to excrement disposal, nor to milk-supply, but to a public water-supply common to the invaded parts of each district" and to the high-level section of it, which section was shown to have been similarly related to fever prevalence in previous years. In a subsequent report Dr. Thomson shows that this water was contaminated by being collected from gathering grounds which "contained a great deal of cultivated ground which is manured not only with farmyard but also with privy midden refuse, and sewage from villages as well as from detached houses finds its way into the water-supply, more especially on the high-level gathering grounds."

In 1898 Dr Bruce Low reported on an outbreak of fever at Penrhynside (Carnarvon) The nature of this disease was "at first obscure; some cases resembled typhus, others cerebro-spinal fever, and a few influenza; ultimately malady regarded as true enteric fever; infection imported. The water-supply was from an extension of the Llandudno water-mains. At the time of the outbreak the pipes were encrusted and partially blocked. There was no evidence of pollution of this public water-supply The service was scanty and intermittent, "causing the villagers to seek temporary supplies from springs and spouts on slopes of hillside below village Some of these temporary supplies were most probably polluted by washing of surface filth from village down the slopes by heavy rainfall; hence the spread of the disease"

In 1897 Dr. Bruce Low reported on an outbreak of typhoid fever in the Horsforth Urban District (Yorks.). He found that the gathering ground for the water company was high-lying pasture land dressed freely with stable manure and night-soil and that the sewage from farmhouses and also road washings reached the feeders of supply. "Sand filtration was provided, but in summer months as well as at other times it has been customary to turn on unfiltered compensation water to the town mains to augment supply. Following use in September, 1898, of this unfiltered water there occurred a sudden outbreak of enteric fever in October, attributed by the medical officer of health to polluted water of company's service."

In 1898 he also reported on a sudden outbreak of typhoid fever in December, 1899, in the town of Camborne (Cornwall) and an adjoining parish and village. The only condition common to these three places was their water-supply. "One of the two sources of this supply was from *some springs at Boswyn, to augment which section of the* supply a pipe had been laid from the brook to the service tank. The brook was *fed freely by surface water* from a hillside on which, in a cottage, four cases of enteric fever occurred in October and November, 1897. The bowel discharges of these cases reached a pond close to the house which had no privy. In wet weather the pond overflowed and the water from it ran down a channel to the brook, entering at about 100 yards above the intake pipe of the Camborne Company In mid-November the rainfall was excessive and the flood-water washed out the pond and carried the pollution to the brook and thence to the service reservoir. After the removal of the pipe connecting the brook with the reservoir, and after cleansing the service tank and flushing the mains, the epidemic abruptly ceased."

In 1897 Mr. J. S Davy, Dr. Theodore Thomson, and Mr G. W. Willcocks were appointed by the Local Government Board to inquire into an epidemic of typhoid fever at Maidstone. This had been already investigated by Mr. M. A. Adams, the medical officer of health, who had come to the conclusion that it was caused by the pollution of some of the springs supplying the water company's water by the excremental matters from a colony of hop-pickers. The arguments used against this view were that there were cases of typhoid fever in Maidstone before the hop-pickers came at all, that many of the public sewers and house-drains and other sanitary appliances were in an extremely defective condition, so that contaminated air from them gained access to the houses, and that after the suspected water was cut off and a further period of 16 days allowed for incubation of any subsequent cases 357 more cases occurred in the town, which could not have been caused by the water—a contention which the inspectors say in their judgment is "in the main a just one," and that therefore the causes which operated to produce them might produce the whole epidemic, a condition which the inspectors admitted "is probably in some degree admissible." Nevertheless, the inspectors came to the conclusion that the epidemic was caused "by the pollution of the water supplied by the Maidstone Company *from their Farleigh sources.*"

(To be continued.)

RESULTS OF THE VACCINATION OF 1060 ADULTS.[1]

BY H. SINIGAR, M.D. LOND.,
ASSISTANT MEDICAL OFFICER TO LEAVESDEN ASYLUM.

VACCINATION statistics are amongst the commonest and best known statistics on medical subjects, yet most vaccination statistics are founded on cases which are seen but twice by the vaccinator It is somewhat rare for a practitioner to have an opportunity of observing the whole clinical course of vaccination in every individual whom he vaccinates; therefore the results obtained recently at the Metropolitan Asylum, Leavesden, may be of interest, especially at the present time.

It may first be pointed out that only adults (of ages varying from 16 to 95 years) are dealt with, and that most of the cases are revaccinations This paper dwells more particularly on the clinical aspect of vaccination itself, and little reference will be made to the relationship between small-pox and vaccination. The figures given apply only to the *female* staff and female patients, a total of 1060 individuals No very unusual phenomena were observed, but the cases were sufficiently numerous, perhaps, to enable some conclusions to be drawn as to the frequency of occurrence of some of the common complications and sequelæ.

---

[1] A paper read before the Windsor and District Medical Society.

Of the material constituting the greater part of these cases it may be said that an asylum population should not be compared with a general one. It is true that, speaking broadly, the patients show to a marked degree a distinct deficiency in their sensory systems, and thus may give little or no evidence of slight disorders; but this is outweighed by the fact that they are remarkably prone to epidemic diseases, and that such diseases amongst them are usually of severe type. On the whole, therefore, it is probable that the results given below will not differ much from those obtained in ordinary practice.

The first important fact noted was the want of uniformity in the potency of different strains of lymph. Much has lately been written upon this subject, and our experience at Leavesden fully confirms the complaints which have been recently appearing in the medical press. Lymph was used from three different sources; lymph from source A proved to be almost inert, lymph B was not much better, but lymph C gave such excellent results that it was at once made the standard supply.

The figures for the female staff are given first separately, chiefly because they serve to illustrate very well the variable potency of lymph A and lymph C. Table I. was compiled after all doubtful cases and failures had been vaccinated at least three times.

TABLE I.—*Showing the Results of Vaccination among the Female Staff.*

	Cases.	Successful.	Unsuccessful.	Percentage of successes.
Primary vaccinations... ...	2	2	0	100
Once vaccinated	82	81	1	98·7
Twice vaccinated	17	14	3	82·3
More than twice vaccinated.	4	4	0	100
Totals...	105	101	4	96·2

The inertness of lymph A was well shown by vaccinating 49 nurses with it; there were only eight successes, 16 being doubtful and 25 complete failures. The 16 cases which were "doubtful" were revaccinated with lymph C, and in every case good vesicles were obtained. The 25 cases of failure were also revaccinated with lymph C when 21 successes were obtained, only four being failures. The potency of lymph C was confirmed by the next 41 vaccinations of the staff with it, all of which were successful.

At the outset a very important question had to be decided—namely, on what grounds should it be deemed advisable not to vaccinate a patient. Small-pox existed in the metropolis and the object of the general vaccination was to prevent the disease making its appearance in the asylum. The important safeguard of stopping the regular visiting to the patients had already been taken, but there still remained the every-day traffic between the asylum and the metropolis and the visits of the friends of those patients who were seriously ill. The weakest patients, therefore, were just those patients who came most in contact with London and were consequently most exposed to possible infection. On these grounds it was decided to vaccinate every patient with one exception—that of a patient who had obviously only a few days to live. It is pleasing to report that the vaccination of these weakly patients produced no untoward effects.

TABLE II.—*Showing the Results of Vaccination among the Female Patients.*

Total cases.	Successful.				Fair or doubtful.		Failures.
	Four vesicles.	Three vesicles.	Two vesicles.	One vesicle.	Four vesicles.	One, two, or three vesicles.	
	890	3	2	1	42	9	
955	896				51		8

Adding the totals of staff and patients together the results are that out of 1060 vaccinations, 997, or 94 per cent., were successful; 51, or 4·8 per cent., were doubtful; and 12, or 1·2 per cent., were failures.

An attempt was made to ascertain the numbers of those who had never previously been vaccinated, and also of those who had suffered from small-pox.

TABLE III.—*Giving the Cases in which there was no Evidence of Previous Vaccination.*

Cases.	Successful.	Failures.	Percentage of successes.
89	87	2	97·7

TABLE IV.—*Giving the Cases of Revaccination only.*

Cases.	Successful.	Doubtful.	Failures.
971	910 (93·7 per cent.)	51 (5·2 per cent.)	10 (1 per cent.)

TABLE V.—*Giving the Cases in which there was Evidence of Small-pox previously.*

Cases.	Successful.	Doubtful.	Failures.
45	40 (88·8 per cent.)	1 (2·2 per cent.)	4 (8·8 per cent.)

With regard to the great majority of the cases nothing more need be said than that they ran a perfectly typical course. Cases of acceleration and retardation of the pocks were observed but unfortunately records of them were not kept. Dealing first with what may be called preventable sequelæ, papules from irritation from the dressings, acne, boils, abscesses, and carbuncles were met with. Such sequelæ depend largely upon the personal cleanliness of the patient; it need hardly be pointed out that in many of the patients personal neglect is the rule, and that such patients, in spite of the vigilant attention of the nurses, will be prone to septic conditions of the skin.

Papules from irritation from the dressings.—These occurred in 24 cases, or 2·2 per cent., and in some the papules became pustular. They began as a rule close to the vaccinated area; another favourite site was over the deltoid, where the skin was rubbed by the bandage. All the cases quickly yielded to simple treatment.

Acne or pustules spreading beyond the vaccinated area.—This condition occurred in six cases. Two began on the tenth day after vaccination, one of which cases involved only the vaccinated arm; in the other case the arm and the leg on the vaccinated side were affected. One case began on the twelfth day when acne appeared on the arms and the trunk. One case began on the fourteenth day with pustules on the arms, the elbows, and the buttocks, and another on the seventeenth day with pustules on the arm and the trunk. All yielded to treatment in from seven to 14 days.

Boils.—These were late sequelæ and were noted in 21, or 2 per cent., of the cases The earliest case appeared on the tenth day, one appeared on the sixteenth day, four on the twenty-second day, one on the twenty-fifth day, two on the twenty-seventh day, two on the twenty-eighth day, four on the twenty-ninth day, three on the thirtieth day, and three on the thirty-fifth day after vaccination. It is interesting to note that 13 of the cases occurred in the epileptic ward, and the epileptic patients include some of the dirtiest and most troublesome patients in the asylum. None of these patients were taking bromides. As a rule the boils were small and they were nearly all situated on the vaccinated arm and shoulder.

Carbuncles.—Carbuncles occurred in a phthisical patient of very dirty habits. She developed several boils on the back on the twenty-eighth day after vaccination. These she was continually scratching and rubbing, and in a week's time she had one large and two small carbuncles on the back, which required incisions.

Abscesses.—These occurred in four cases. One appeared 20 days after vaccination in the lower half of the posterior triangle of the neck. It was an ill-defined abscess and was

TABLE VI.—GIVING PARTICULARS OF 23 CASES IN WHICH ERYTHEMA FOLLOWED VACCINATION.

Simple Erythema (Four Cases).

No.	Years of age	Date of the appearance of the rash.	Nature of the rash.	Distribution of the rash.	Duration of the rash.	Condition of the arm.	General symptoms.
1	—	Tenth day after vaccination.	A diffuse blush.	On the arms, the chest, and the legs.	48 hours.	Good vesicles; the arm slightly inflamed.	Temperature 99° F.; pains all over.
2	55	Thirteenth day after vaccination.	A bright-red blush.	On both elbows.	36 ,,	Good vesicles; the arm not inflamed.	None.
3	44	Third day after vaccination.	An erythematous blush.	On the arm and the wrist.	24 ,,	Arm not inflamed; the pocks matured normally.	,,
4	40	Thirteenth day after vaccination.	A bright blush.	On the arms.	36 ,,	Good vesicles; the arm not inflamed.	,,

Erythema of Punctate Type (Three Cases).

No.	Years of age	Date of the appearance of the rash.	Nature of the rash.	Distribution of the rash.	Duration of the rash.	Condition of the arm.	General symptoms.
1	45	Eleventh day after vaccination.	Closely set vivid red spots of about the size of a pin-head.	On the forearms and the legs	48 hours.	Good vesicles; the arm not inflamed.	None.
2	25	Thirteenth day after vaccination	Finely punctate rash; the spots closely set and slightly raised.	On the abdomen and the groins.	36 ,,	Good vesicles; the arm rather inflamed.	,,
3	60	,,	Bright-red punctiform erythema.	On the buttocks, the back, and the elbows.	48 ,,	Good vesicles; the arm not inflamed.	,,

Erythema of Papular or Urticarial Type (Six Cases).

No.	Years of age	Date of the appearance of the rash.	Nature of the rash.	Distribution of the rash.	Duration of the rash.	Condition of the arm.	General symptoms.
1	26	Sixteenth day after vaccination.	A profuse crop of pale flattened papules	On the chest and the back.	36 hours	Good vesicles; the arm not inflamed.	None.
2	—	Eighth day after vaccination	Small red discrete papules, some surrounded by an erythematous area.	On the arms, the hands, and the legs.	4 days.	Good vesicles; the arm rather inflamed.	Headache and malaise.
3	—	Twelfth day after vaccination	Fugitive urticaria.	On the arms, the legs, and the trunk.	5 ,,	The arm took very slightly and was not inflamed.	Temperature 103° F.; malaise, itching.
4	—	Eighth day after vaccination.	Discrete red papules.	On the forearm and hand of the vaccinated arm.	48 hours.	Good vesicles (primary vaccination); the arm much inflamed.	Malaise and headache.
5	71	,,	Flat, discrete, pale red papules.	On the elbows, the forearms, and the shoulders.	48 ,,	Good vesicles; the arm not inflamed.	None.
6	73	,,	Flat discrete papules.	On the arms and the shoulders.	48 ,,	,,	,,

Erythema Multiforme (10 Cases).

No.	Years of age	Date of the appearance of the rash.	Nature of the rash.	Distribution of the rash.	Duration of the rash.	Condition of the arm.	General symptoms.
1	60	Tenth day after vaccination	Irregular blotches of bright red erythema, fading on pressure.	On the arms, the legs, and the buttocks.	48 hours	Good vesicles; the arm not inflamed.	None.
2	44	Eighth day after vaccination	Large irregular patches of brilliant erythema, diffuse, duller red and not *fading on pressure on the* legs.	On the arms, the shoulders, the trunk, and the legs.	4 days.	Good vesicles; the arm moderately inflamed.	Malaise for 24 hours.
3	71	Ninth day after vaccination.	Bright red blotches.	On the arms, the body, and the legs.	48 hours.	Good vesicles; moderately inflamed.	Slight malaise.
4	61	Eleventh day after vaccination	Brilliant red irregular blotches; next day a dull punctiform rash.	On the arms and the legs.	,,	Good vesicles; not inflamed.	None.
5	60	,,	Diffuse vivid red erythema; in parts large irregular blotches.	On the trunk, the arms, and the legs.	,,	,,	,,
6	69	,,	Brilliant red papules on the legs; a diffuse red blush on the arms; next day a dull, red erythema on the limbs and fresh papules, on the next day areas of erythema circinata spreading over the trunk.	On the trunk, the face, the arms, and the legs.	6 days	,,	Loss of appetite; malaise; temperature 100° F.
7	80	Ninth day.	Blotches of bright-red erythema, with slightly raised and well-defined margins.	On the trunk.	48 hours	,,	None.
8	58	Tenth day after vaccination.	Irregular patches of bright red erythema and a few papules.	On the elbows, the wrists, and the knees.	48 ,,	Good vesicles; moderately inflamed.	,,
9	64	,,	Vivid red blotches with well-defined and sinuous margins. Fading on pressure.	On the trunk, the legs, and the arms.	48 ,,	Good vesicles; the arm inflamed.	Slight malaise.
10	26	,,	Irregular red patches.	On the arms and the trunk.	36 ,,	Good vesicles; the arm not inflamed.	,,

accompanied by loss of appetite and malaise. In another case a subcutaneous abscess appeared between the pocks on the twenty-fourth day. In another case a few boils appeared on the arm on the twenty-ninth day; these were followed by cellulitis of the arm and suppuration. Lastly, a small superficial abscess occurred in the axilla of a patient on the thirty-second day. All the cases healed rapidly and well after incision.

Reappearance of old skin trouble.—This was noted in a woman who had been long subject to psoriasis. A small patch appeared on the trunk on the thirteenth day; it cleared up in a week.

Eczema.—There were three cases in which eczema appeared. One was that of a nurse in whom a crop of papules appeared on the wrists and forearms on the tenth day after vaccination; the papules rapidly became vesicular. There was no constitutional disturbance and the rash cleared up in a week. In the other two cases a papular eczematous rash appeared 28 and 36 days respectively after vaccination, but lasted a few days only.

Herpes.—In one case a patch of herpes rather larger than a shilling appeared on the cheek 18 days after vaccination. It rapidly cleared up.

Erythemata.—These occurred as simple erythematous blushes, as finely punctate erythemata, as erythema of papular or urticarial type, and as erythema multiforme. In all there were 23 cases, or 2·1 per cent. of the total vaccinations. The erythematous rashes occurred in these cases as a rather later phenomenon than is stated by Acland in Clifford Allbutt's "System of Medicine." He gives the time of occurrence of the erythematous rashes as from the third day up to the time of maturation of the pock. In these cases one appeared on the third day, five on the eighth day, two on the ninth day, five on the tenth day, four on the eleventh day, one on the twelfth day, four on the thirteenth day, and one on the sixteenth day after vaccination. All ages were liable, four cases occurring in patients over 70 years of age. As a rule there was a little constitutional disturbance, but in several of the cases the patients made no complaint. In only one case was there severe constitutional disturbance and that patient recovered rapidly when the rash faded. The average duration of the rash was about 48 hours, but in the severe case above mentioned it lasted six days. Rashes occurred in patients whose arms ran a perfectly aseptic course; they were therefore regarded as a true vaccinial complication—a conclusion, however, which can only be accepted with reserve, as septic absorption gives exactly similar rashes. The rash looked much more alarming than the actual condition of the patient warranted, for in several cases with most vivid rashes there was practically no disturbance of the general health of the patient.

Auto-inoculation.—In five cases there was auto-inoculation. In three there was a small vesicle about one inch distant from the nearest inoculation. In one case there was an outlying vesicle two and a half inches from the nearest inoculation and in another there were two vesicles half an inch away from the nearest original insertion. These vesicles matured at the same time as the original inoculations.

Generalised vaccinia.—Of this condition there was one case in a patient, aged 31 years. Four good vesicles were inspected on the eighth day. On the next day additional vesicles appeared on the arms, the face, and the chest. The vesicles were not compound, were oval in shape, about a quarter of an inch long, and contained pale turbid lymph. Each was surrounded by a slight inflammatory areola and there was some malaise. A few more vesicles appeared in successive crops during the next three days, then they cleared up quickly and well, leaving no scar.

The very slight disturbance of the general health of the patients by vaccination was very noticeable. It was found convenient to vaccinate all the patients in a pavilion on the same day. It therefore happened that there were under observation from 120 to 150 patients in each pavilion and all in the same stage as regards their vaccination. Speaking broadly, it may be stated that the appetites of those vaccinated remained good, the patients looked well, and those of them who were usually engaged in the domestic work of the asylum were able, with very few exceptions, to perform their duties without difficulty. Of the nurses three were sent off duty, one of them being a case of primary vaccination and another was a rheumatic subject whose indisposition was possibly as much rheumatic as vaccinal. The effect produced in the minds of all who observed the cases was that the consequences of vaccination had been unduly magnified by alarmists. Cases, of course, occurred in which there was considerable constitutional disturbance, with headache, pains all over, lassitude, and pyrexia, but they formed a very small proportion of the whole number of cases.

With regard to what may be called the preventable septic complications of vaccination, most will agree that the figures are not unduly high, yet it must be remembered that many of the patients are dirty rather than cleanly in their habits, and are therefore predisposed by their habits to such complications. In ordinary practice these figures should come out very much lower.

It does not require any very vivid imagination to picture the state of an institution such as Leavesden Asylum if small-pox broke out amongst the patients, but no one would have guessed from an ordinary inspection of the asylum that the whole of the patients were down with vaccination. It is very satisfactory to be able to report that although the feeble and the aged patients were all vaccinated yet no unfavourable results followed.

Table V. is of interest in showing the high percentage of successful vaccinations among those persons who had previously had small-pox, a fact which tends to show that vaccination is a better protection against small-pox than small-pox is against vaccination.

With regard to the lymph used, it is important to note that a staphylococcus was grown from it. In spite of this the majority of the arms showed only the inflammatory reaction of vaccinia, so that it is probable that those arms which were much inflamed were infected subsequently to the vaccination. In a few cases, however, it was thought possible that the staphylococci in the lymph were responsible for an inflammatory blush which appeared on the third day at the seat of inoculation and which was accompanied by enlargement and tenderness of the axillary glands and œdema of the arm. The inflammatory symptoms in these few cases subsided before the pock matured and the vaccination afterwards ran a normal course in them. It is most unsatisfactory to know that there is useless lymph on the market—a source of very grave danger both to the public health and to the reputation of vaccination. It should be our duty as medical men to guard jealously the fair fame of vaccination from the slanders of the anti-vaccinationist, and to do this we must vaccinate efficiently. This is not the place to discuss the question of efficient vaccination, but it will suffice to assert that it is possible for revaccination to produce vesicles as typical as those of primary vaccination and in such cases the individual may be regarded as efficiently vaccinated. For this efficient vaccination a potent lymph is essential, and it should be our duty to produce a lymph which we can be sure will always give good vesicles except in those cases protected by previous vaccination, by small-pox, or by natural immunity. The bacteriologist has still to discover the specific active agent of vaccinia; when that has been discovered it may then be possible to use a standardised lymph free from extraneous micro-organisms. It is surely not improbable that in the future there will be vaccinia units injected in known doses and with as little fear of septic complications as there is at present in the injection of antitoxins. The complications of vaccination after all are chiefly due to neglect of surgical principles, and the vast majority of bad arms with their accompanying malaise are preventable.

At this particular season the slight constitutional disturbance caused by an aseptic vaccination cannot be too strongly emphasised, and even weakly people can therefore be told that with suitable care they may be safely vaccinated.

King's Langley.

BRISTOL ROYAL INFIRMARY.—The annual meeting of the governors of this institution was held on March 25th, under the presidency of Sir Charles Cave. The medical report stated that 3246 in-patients had been admitted during 1901, against 2986 in 1900; the out-patients numbered 38,617, compared with 38,671 in the previous year. 410 maternity cases had been attended at the patients' own homes and 417 patients had been sent to the Queen Victoria Jubilee Convalescent Home. The financial statement showed that the total ordinary income for the year amounted to £11,467 and the total ordinary expenditure to £15,252. The total unfavourable balance of the infirmary now amounts to £9332. The committee has made arrangements for the introduction of the Finsen light treatment for lupus. The chairman made a strong appeal for increased financial support.

THE SURGERY OF NON-MALIGNANT GASTRIC ULCER AND PERFORATION.

By C B. KEETLEY, F R.C.S. Eng.,
SURGEON TO THE WEST LONDON HOSPITAL.

(Concluded from p 887)

General observations on certain gastric troubles such as perforation and on some operative methods applied in their treatment were published in The Lancet of March 29th, p. 884 An analytical table was appended. It now remains to describe in detail such of the cases as are not reported elsewhere

Case 1 *So-called "spontaneous" rupture of the stomach, excision of the strictured pylorus and the adjacent part of the stomach, which was the site of the rupture, three and a half hours afterwards, recovery* —The patient, a man, aged 42 years, when admitted on Dec. 16th, 1899 was suffering from severe pain in the epigastrium. The pulse was good but the respirations were rather rapid. The abdomen was moving slightly with breathing, but it was tender all over, especially in the region of the stomach. Liver dulness was present. The patient had suffered from "indigestion" for months, with attacks of vomiting, but he had never brought up blood He had, however, passed dark coloured motions (melæna ?) and he had suffered from piles. At noon on the day of admission, when lifting something heavy, the patient was seized with a momentary sharp pain in the epigastrium and severe vomiting He walked indoors and drank some bovril. The pain then became excruciating and it spread all over the abdomen. Dr A. H. W Clemow saw him and, diagnosing gastric perforation, gave a quarter of a grain of morphia hypodermically and sent the patient into hospital for operation *Mr Keetley saw the case at 3.30 P M* and operated immediately

Operation.—A four inch epigastric incision parallel to, and to the left of, the middle line exposed the stomach, which showed a transverse tear three-quarters of an inch long on the anterior surface close to the pylorus, which was itself evidently cicatricially contracted. There was a considerable amount of fluid in the peritoneal cavity (probably bovril, mucus, and serum) The pylorus was slit up longitudinally, when its lumen was found to be narrowed to one-quarter of an inch in diameter There was no ulceration but cicatricial tissue had taken the place of the muscular coat Partly because this had led to the rupture and partly because of the possibility of its being malignant it was resolved to excise the pylorus. No enlarged or hard glands were discoverable. The part torn was not obviously diseased at all. The stomach was emptied by passing a rubber tube through the rent and then handed to an assistant. A temporary rubber tube was passed round the duodenum. Excision was performed freely on the stomach side so that the gastric opening was larger than the duodenal. Its superfluous part was sutured up and the remainder was united to the duodenum by interrupted fine silk sutures (sero-muscular only) Before the suturing the abdominal cavity was dried and cleansed by swabs and all its recesses were douched out with hot neutral saline, chiefly by means of a tube passed in through a hypogastric counter-opening A large drainage tube was left in a counter-opening in the right loin and shortened from time to time until at last it was removed.

Recovery was uneventful. There was no rise of temperature except on the eighteenth day and again on the twentieth day The patient was discharged five weeks after admission and was seen to be in good health some months afterwards. The patient was shown at the West London Medico-Chirurgical Society (The notes are by Dr J Matthews Duncan)

Case 2. *A patient treated in hospital for chlorosis and gastric ulcer is discharged apparently well but returns in three days with a perforation, laparotomy 24 hours afterwards, complete recovery, health and digestion still apparently good five months after operation.*—The patient, a girl, aged 17 years, was admitted into the West London Hospital on March 31st, 1901, with the following history She had been discharged from a medical ward only three days before, where she had been treated by milk diet, rest, iron, aloin, and sulphate of magnesia, for chlorosis with possibly gastric ulcer The brief notes recorded "uninterrupted improvement, abdominal tenderness disappeared" The notes on the blood during this stay were "hæmoglobin, 45 per cent., red cells, 3,490,000, white cells, 7000" The patient had never vomited up to that time but had had pain in the stomach after food for seven weeks. On March 30th, after taking a light tea, she went out. Two doors from home, being seized with a violent pain in the left side (gastro-splenic region) and with difficulty in breathing she returned home and went to bed. She shivered and felt cold. Mr J Hepburn gave her a small dose of opium. She slept and "felt better the next morning" She lived opposite to the hospital and Dr Otto F F Grünbaum went over to see her at 3.30 P M the next day She would not then acknowledge any abdominal tenderness, but her respirations were rapid, of the so-called hysterical type, her pulse was 104, of good volume and tension, and the liver dulness was diminished in intensity, its lower limit being one or two centimetres above the costal margin. The abdomen, though not distended, "felt firm" "Some collapse" (?) In the left flank there was some dulness, its anterior margin varying with the position of the patient. The temperature was 98·4° F and the pulse was 108. Taking these facts and the history into consideration Dr Grünbaum diagnosed perforation of a gastric ulcer At 5.30 P M the breathing was more rapid, the pulse was 110 and not of such good volume as before, the temperature was 102°, and there was slight evidence of free fluid in the abdomen. At 6.30 P M laparotomy was performed.

Operation.—Dr. Grünbaum gave an anæsthetic—gas and air, and later oxygen, with occasionally "a few whiffs of ether as a stimulant.' A median incision was made above the umbilicus. A few bubbles of inodorous gas or air escaped There was great distension of both the stomach and the colon, especially of the latter, so great as to necessitate puncture of both in order to make room for further procedures. On passing the fingers between the anterior wall of the stomach and the liver *sero-purulent fluid* escaped The anterior wall of the stomach, all along the lesser curvature, from near the pylorus to as far as the œsophageal opening and for a breadth of several inches was plastered over with recent lymph and had evidently been loosely adherent to the liver, encapsuling the fluid which I had just let out The perforation was not seen, it was probably hidden beneath the lymph which it was not thought advisable to disturb roughly However, all these parts were carefully swabbed and cleansed and a thin iodoform gauze drain or tampon was spread out a little and passed well back, so as to cover the lymph coated area. A suprapubic incision was then made, pus was found in the pelvis and that cavity was carefully swabbed out. Serous or sero purulent fluid was found in the left flank but not in the right flank. Three rubber drains, each about as thick as the little finger, were placed in the pelvis and through two special lateral incisions in the splenic and right hepatic fossæ of the peritoneum respectively The right was removed in three days and the others were gradually shortened in a few days more Feeding by the mouth was not commenced till the twelfth day, but the convalescence was uninterrupted. The gastro-hepatic gauze tampon was removed every two days, several times, on each occasion being replaced by a smaller piece The tubes were removed and shortened at the same time. On the sixth day the nutrient enemata were returned and the bowels acted in the bed A pint of hot water was henceforth injected into the rectum an hour before each nutrient enema. All the water was retained. The temperature which was 102° on admission was 101 4° at 6 P M the day after operation, and it sank quickly to normal where it remained after the fifth day The patient remained for five months afterwards free from indigestion or other gastric troubles but still rather anæmic. (The notes are by Dr O Inchley)

Case 3. *Perforation of gastric ulcer, operation 26 hours afterwards, recovery* —The patient, a female, aged 21 years, was seen by Dr D Fairweather of Wood Green on Dec 26th, 1901 He immediately sent for Dr C O Hawthorne and a surgeon and after a consultation between those gentlemen Dr R. S Dickson, Mr E. J Eedle, and myself operation was performed without delay The perforation had occurred more than 24 hours before. The whole of the lesser cavity of the peritoneum was full of thick lymph patches and fluid the right flank and the pelvis were full of sero-purulent fluid and a little lymph, and there was one patch of lymph on the anterior wall of the stomach. After careful swabbing four iodoform gauze drains and one long rubber drain (pelvic) were inserted. Two incisions—epigastric and hypogastric—were made. Recovery was uneventful and the patient is now apparently quite well (12 weeks after operation). This case will be published in full.

CASE 4. *Perforation of a gastric ulcer; operation 26 hours afterwards; recovery.*—The patient, a young woman, aged 24 years, was admitted into the Chislehurst and Cray Valley Cottage Hospital on the morning of Jan. 22nd, 1902, under the care of Mr. Hugh Lawson, and was operated upon on the same afternoon with his assistance and that of Dr. T. M. Callender more than 24 hours after perforation. This case resembled greatly the preceding one, except that the perforation was in the anterior wall, near the lesser curvature, and a little towards the cardiac end. It was closed by two rows of fine silk Halsted's sutures. Swabbing was employed, followed by gauze drains, &c., as in the preceding case. The course of the case was uneventful. The patient is now (six weeks after operation) up and on solid food and is free from pain. This case also will be published at greater length.

CASE 5. *Perforation of a gastric ulcer; peritonitis; operation on the fifth day; afterwards perforation of a second ulcer; parotitis; perihepatic abscess; pleurisy; death on the thirteenth day.*—The patient, a female, aged 23 years, was admitted to hospital on the medical side on Dec. 2nd, 1899, complaining of abdominal pain. On the previous night she had been attacked with severe pain in the left side of the abdomen and she vomited a little brandy which was given. She was sent to bed. She had had dyspepsia off and on for some years but never vomited blood. Next day (Dec. 3rd) the patient did not look ill, except that she was anæmic. There was tenderness in the epigastrium in the middle line. The abdomen was not distended and it moved well. The tongue was clean. The temperature, which on the previous day had been 101·4° F., was on this day 101° in the evening and on the 4th it was 99·8°. But on these two days the patient was getting worse. The abdomen was more distended and tympanitic. The tongue was dry and the pain was worse. The bowels had not been opened since admission. On Dec. 5th Mr. Keetley was asked to see the case and he operated at once.

Operation.—There was a large escape of gas on opening [illegible] peritoneal cavity. A small perforation was found in the [illegible]erior wall of the stomach which was covered by a good [illegible]l of lymph. The lower margin of the great omentum was [illegible]dherent to the anterior abdominal wall in such a way as to have apparently cut off and protected the pelvis and small intestine from infection, the peritoneum above being covered with lymph. The ulcer was excised and closed by sutures, perforating all coats and tied with the knots inside (through a small incision made on purpose close by and afterwards itself closed). The right flank over the kidney and under the liver was examined with a sponge but no fluid was found. A thin layer of iodoform gauze was placed on the sutured stomach surface and, with a rubber drain, brought out of the wound. Nutrient enemata were ordered. On the day after the operation (Dec. 6th) the gauze was removed. As the skin sutures looked tense some were removed and boric acid fomentations were applied. On the 7th the pulse was rapid. Milk was taken by the mouth as well as by the rectum. The tongue was very dry and cracked. On the 8th the bowels were moved six times through the night (the first motions since before the perforation occurred). The nutrient enemata were stopped and an enema of starch and five grains of Dover's powder was given. "Dressed to-day and condition of abdomen good." On the 12th the patient had developed parotitis on the right side. The mouth was being frequently cleaned with glycerine of borax. The general condition was worse but there was no pain or tenderness in the abdomen. There was a dirty discharge from the wound, seeming to contain bile. There was pain on the right side; a friction rub was heard. There was some dulness at the right base. A subphrenic abscess was suspected but the patient's condition seemed to be too bad for any operation. The pulse was 140, the respirations were 48, and the temperature was 102°. The patient died on the 13th.

Post-mortem examination.—There were an abscess around the right end of the right lobe of the liver and *a second perforation of the anterior wall of the stomach.* There was pus in Douglas's pouch. The intestinal coils on the right side of the abdomen were infected and there was a good deal of lymph between them. In the left flank they were free from peritonitis. That part of the anterior wall of the stomach which was the site of the two perforations was bathed with dirty-looking discharge and covered with lymph. Both openings leaked and the one which was sewn up at the operation had sloughing edges.

Remarks.—When two days before death a dirty, bilious-looking discharge was observed in the wound I ought immediately to have opened it up and searched for the cause. I was held back by one of the two reasons which prevented me from searching for a subphrenic abscess—viz., the bad general condition of the patient who was unfit to take a general anæsthetic or to go through what might prove to be an extensive operation under local anæsthesia. The second perforation certainly took place after the operation, because all that part of the stomach wall in which it occurred was well seen and examined. I think the leakage from it led to the fatal termination by polluting the whole wound and perhaps by percolating down into the right suprarenal fossa. The pus in the pelvis may have been secondary to either the first or the second perforation. It must not be forgotten that this case was not operated on until four days after the first perforation. (The notes are by Dr. Matthews Duncan.)

CASE 6. *A large, ragged perforation of the posterior wall of the stomach; general suppurative peritonitis of both greater and lesser cavities; the patient first seen when moribund on the fifth day; the peritoneal cavity drained and douched with neutral saline solution every two hours; artificial anus (ileum); death 34 hours afterwards.*—The patient, a female, aged 23 years, was admitted into the West London Hospital on Sept. 26th, 1900. The patient was brought into the theatre from outside the hospital in a moribund condition, presenting the appearance of a patient with suppurative peritonitis. The abdomen was as hard as a board. The pulse was 140.

Operation by Mr. Keetley.—The patient was put lightly under ether. An incision was made in the middle line three inches long from the umbilicus down, with two sweeps of the knife. There was no bleeding, only a slight oozing at the venous points. A tube of rubber was put deep down into the pelvis. On either side, at the most dependent part between the ribs and the iliac crest a like incision was made. From the flank wounds to the hypogastric wound drainage-tubes were pulled through by large Spencer Wells forceps till they emerged at both ends. A fourth incision was now made at McBurney's point through which a loop of ileum was drawn, opened, and the edges then sutured to wood-wool pads. The peritoneal cavity was then irrigated with five pints of warm neutral saline solution and the patient was removed to a ward. She was put on milk, soda-water, barley-water, or beef-tea to two ounces hourly, gradually increased to three ounces. There was no vomiting after the operation and flatus was passed both through the artificial anus and the rectum. At intervals of two hours three pints of warm saline solution were irrigated through the drainage-tubes and the dressings were changed. There was no improvement in the pulse, the temperature (about 102°), or the respiration. At 12.30 P.M. the patient started singing for a short time. After that she became rapidly worse, breathing more rapidly, with the pulse running and uncountable. This was 33 hours after operation. The temperature rose to 106·2°, and after death, at 1.30 A.M., to 107·3°.

Post-mortem examination.—The abdominal cavity was filled with foul and purulent fluid. The liver and stomach were covered with the material. Other organs had been partially cleaned by the irrigation. The perforation, which was found on the posterior surface of the stomach near the lesser curvature and nearer the pylorus than the cardiac end, was of the size of a halfpenny, with thick edges. There was a large amount of shreddy material attached to the under side of the diaphragm, just opposite to the corresponding site of the ulcer. There were pleural adhesions over the lower surface of the left lung.

Remarks.—This patient's acute troubles had begun four days before she was seen by me. After warning her friends of the practical hopelessness of the case I had her removed at once to the hospital and I operated as above. She was quite unfit to stand any search for the cause of the peritonitis. The drainage, the douching, and the artificial anus relieved the patient for the time and *might* have saved her had not the mischief been so great around the liver and in the lesser peritoneal cavity and the perforation so large. This is a type of cases which occur every day and are sacrificed by not calling in the surgeon at the first to clear up the diagnosis. It should be contrasted with Cases 1 and 2. It was a mistake to feed the patient by the mouth, but we were tempted to do it by her depressed state and by the readiness with which she took and retained liquids. (The notes are by Dr. J. Catto.)

CASE 7. *Perforation (?) and hæmorrhage; rest and rectal feeding; improvement for 10 days; then death from sudden and severe hæmorrhage.*—The patient, a married woman, aged 28 years, was under the care of Dr. C. F. L. Dixson of Brentford. She had been treated for dyspepsia for some time. After retiring late on April 6th, 1900, she awoke with "agonising pain" in the abdomen and great collapse. She rallied from this, but as the pain and tenderness continued Dr. Dixson got me to see her the next day. We had her removed to the Brentford Cottage Hospital, but eventually refrained from operation partly on account of her own unwillingness and partly because she steadily improved and because also the symptoms suggested at the worst a strictly localised peritonitis. There was no abdominal or thoracic dulness, only moderate distension and no vomiting. The facial expression became good and the patient became cheerful. She was fed strictly per rectum with three ounces of peptonised milk, strengthened by plasmon, every four hours. Hot fomentations were applied to the left side of the abdomen, where the pain was localised. She seemed to be improving for 10 days. She then "had severe hæmorrhage per rectum and died soon after, conscious to the very end," at 11.40 P.M. on April 16th. There was no post-mortem examination, but there can be little or no doubt that this was a case of perforation of a gastric ulcer occurring while the patient was lying in bed with a nearly empty stomach and causing a strictly localised adhesive peritonitis with little or no extravasation. No signs of abscess or of fluid in any part of the abdomen or the thorax were found in spite of repeated examination, and there is a possibility that the perforation may have been duodenal and altogether extra-peritoneal. Doubtless some large vessel was opened either by progressive ulceration or by sloughing and the patient died, as above related, with copious hæmorrhage from the rectum.[1] (The notes are by the matron of the Brentford Hospital. The temperature chart was accidentally destroyed.)

As this record of my experience of non-malignant gastric cases seen in the last four years is meant to be complete the following case should be mentioned.

CASE 8. *Perforation with the stomach probably empty; refusal of operation by the patient; medical treatment; death ultimately with signs of subphrenic abscess and left pleuro-pneumonia.*—A single woman, about 30 years old, was seen by me about three years ago. She had suffered for some time from chronic indigestion. Soon after the preceding midnight she had been seized with great pain in the abdomen and had collapsed. She had had no food since tea-time, about seven or eight hours previously. After a time she rallied but before the breakfast hour she became worse and collapsed again. A medical man was fetched who placed her under my care. I saw her some hours afterwards. She had then rallied once more but she presented symptoms which convinced me that perforation of, fortunately, a probably empty stomach had occurred. I urged her strongly to permit operation but she obstinately refused. I directed her to be fed wholly per rectum and thought that the case might come to nothing worse than a subphrenic abscess, by which time she might be willing to submit to surgical treatment. She ceased to be under my care. In a few days I learned that she seemed so much better that feeding by the mouth was commenced. In a day or two more the temperature began to rise and she eventually died with signs of subphrenic abscess and pleurisy of the left side and without surgical intervention.

CASE 9. *Chronic abscess or fistula in the left anterior abdominal wall traced to beneath the diaphragm and probably having originated in the perforation of a gastric ulcer, erasion, &c., and drainage; cure.*—The patient, a single woman, aged 30 years, was admitted into the hospital on Oct. 26th, 1896. Five years before she had had an attack which was diagnosed as biliary colic and she was said to have passed gall-stones. Chronic indigestion and anæmia had been present ever since. A second attack of "biliary colic" had occurred some months previously. One week after this (June, 1896) peritonitis came on, and towards the end of the same month "some quarts" of pus escaped from an opening at or near the navel. Six weeks previously (September) the discharge had nearly ceased but what was believed to be rheumatic fever supervened. The fever abated and about the same time or a little afterwards the abscess burst open again, discharged freely, and had done so ever since. The patient had "always" suffered from anæmia and at times from "very severe indigestion and neuralgia." The personal and family history otherwise was unimportant. On admission the patient was seen to be pale and thin. The orifice of the umbilical sinus was exceedingly small. There was an area of dulness to the left of, and below, it. The temperature was normal. The patient was now seen by Dr. L. Dobson who immediately placed her under me.

Operation.—On Oct. 27th I proceeded to operate. A sinus or cavity was traced, extending from two and a half inches to the left of and below the umbilicus, underneath the rectus up to the lower surface of the diaphragm as far as the fingers would reach beneath the edge of the ribs. It contained granulations and much foul-smelling pus. The left rectus was divided and after its anterior wall had been freely slit up the cavity was scraped, swabbed, and douched. Finally, a low counter opening was made and three rubber drains were inserted, two between the stomach and the diaphragm and one from the umbilicus to the counter opening.

With regard to the after-history of the case, there was no pain, the wounds gradually completely healed, and the patient put on weight. She was discharged well on Feb. 3rd, 1897. (The notes are by Mr. Ellacombe.)

CASE 10. *History suggestive of old perforation of the stomach; more or less recovered from without operation; but the patient not really well several years afterwards.*—I may mention that I have had in the period covered by these hospital cases a private case with Mr. H. Scott Elliott and Mr. F. W. Way of Southsea in which the history and symptoms point to a perforation of a gastric ulcer 14 months before with localised peritonitis and left pleurisy. The patient cannot be said to be really well yet, although there is nothing now which would quite justify operation. She suffers a great deal from a recurrent skin rash and has occasionally pain and discomfort in the gastric region. It is now four years since the first onset.

CASE 11. *Gunshot (revolver) perforation of the liver and stomach in an infant suffering from rickets and whooping-cough; a sloughing burn on the heel; laparotomy; death on the eighth day.*—The patient, an infant, aged 14 months, was admitted into the hospital at 9.45 A.M. on May 5th, 1901. At 8.30 A.M. his mother, playing with him, accidentally shot him through the abdomen with a revolver, placed close to him. The bullet was found in the bed by Mr. Herbert W. Chambers who cleaned and dressed the wounds and sent the child into the hospital at once. The child was admitted crying and slightly collapsed. The pulse was 168, the temperature was 96·2° F., and the respirations were 40. He was markedly rachitic and had whooping-cough. The collapse increased and was combated by various usual means, including oxygen inhalation. There were two abdominal wounds, one in the middle line below the apex of the ensiform cartilage, and small, the other large and ragged and in the middle of the left flank. This was plugged with a piece of omentum of the size of a florin. At 11 A.M. the patient vomited blood.

Operation.—At 11.30 A.M. on the day of admission operation was proceeded with. Just sufficient anæsthetic (A.C.E.) was given to allow the abdomen to be opened. The child was placed upon two rubber warm-water bottles and his legs were well wrapped in wool. The surface of the abdomen was cleaned and sterilised. A four-inch incision parallel with the left costal margin and starting from the aperture of the entrance was made. There was blood in the peritoneum and a perforation of the liver (left lobe) was still oozing. This was now temporarily plugged with cyanide gauze. The stomach was brought freely into the wound. It showed a small perforation anteriorly, near the pylorus, and a large one of the size of a shilling and very ragged posteriorly, close to the spleen and greater curvature. The omentum was severely bruised but it showed no visible wound. The gastric wounds were each closed by two rows of Lembert's sutures. The stomach was almost empty and nothing which could be distinctly identified as food could be seen in the peritoneal cavity, but I think that there was an appearance as of a little mucus and half-digested milk mixed with the blood found and removed. The prolapsed omentum reduced itself and was carefully cleaned. Counter openings having been made in the splenic and suprapubic regions large drainage-tubes were temporarily inserted and the whole peritoneal cavity was douched with hot sterilised neutral saline solution. The peritoneal wound was closed with fine silk and the muscle and skin were sutured with silkworm gut. The operation lasted just under 45 minutes. An enema of four ounces of peptonised milk was given and the child was put back to bed and well warmed with water-bags. The pulse was 160. At 1.30 P.M. the pulse was 144. The child was warmer and presented a better colour. At 2·30 and at 4.30 P.M. the patient was "doing very well"; the pulse was 130. At 11 P.M. the respirations were 44 and the temperature was 100°. The child was very restless but otherwise he was better. On the 6th the patient was restless but he slept at intervals. The temperature rose to 101·2°, the pulse was 132 and the respirations were 40. The temperature soon sank again to 97·6°. Some "trembling fits" now occurred. Two drachms of milk were administered every hour by the mouth. On the 7th the patient was less restless, there was no vomiting, and he appeared to be comfortable. The temperature was 99°, the pulse was 136, and the respirations were 42. At night the respirations were only 32. The child seemed to be cold and was wrapped in cotton-wool. Whooping-cough returned in the afternoon. On the 8th the patient had had no sleep. The temperatures were 100·2°, 99·2°, and 99·6°, the pulse was 124, and the respirations were 28. The abdomen was soft and not tender. Milk was taken with avidity. On the 9th the patient had passed a quiet night but had had no sleep. The bowels were opened, a partly-formed motion being passed. There were a bad cough and occasional whooping. The temperature was 98·6°, the pulse was 132, and the respirations were 30. The shoulders were raised on a pillow. Another stool—dark and containing a blood-clot—was passed. A nutrient enema which had been administered at five o'clock was returned. After a wash out other enemata were retained. A large blister was discovered on the right heel, probably caused by hot-water bottles, with which he had been carefully warmed since his admission. Great care had generally been taken to wrap them thickly in flannel, but the child's restlessness may have counteracted this. On the 10th a little sleep was gained at intervals. The bowels were opened twice. There was no more blood. There had been no vomiting since the operation. The temperature went up to 102° at 2 A.M.; at 6 A.M. it was 99·4°, the pulse was 128, and the respirations were 32 At 2 P.M. the temperature was 102·2° and the pulse was 154 No coughing had taken place so far on this day. A blister was applied to the heel and the slough was incised beneath. Boric fomentations were employed. On the 11th the patient had slept a good deal but the temperature at 2.30 A.M. had been 104 2°, the respirations 56, and the pulse 140. The child was quiet and he looked as usual except that he was a little paler. At 6 A.M. the temperature was 101·4°; at 12 noon, it was 103·6°, the pulse was 138, and the respirations were 34. At 1.30 P.M. a convulsion occurred. The temperature was 102·8°, the pulse was 160, and the respirations were 52. The convulsions and the rises of temperature were repeated at intervals during the day several times. After 3 P.M. these did not recur. On the 12th the patient was quiet till 7.30 A.M. But then the respirations began to be frequent and at 9 A.M. they were 64, the temperature being 99·6°, and the pulse 132. There were now slight "trembling attacks" and squints were observed. Oxygen inhalations improved the breathing. The abdomen was soft and was moving well. At 10.13 A.M. the child became unconscious and soon afterwards, at 10.50 A.M., he died.

---

[1] This case ought to have been published with the four cases of severe hæmorrhage in THE LANCET of June 8th, 1901, p. 1597; but it was forgotten, doubtless because it was not operated upon. With a case now under the care of Dr. J. Allan of Chislehurst and myself, it makes a total of six *severe* gastric (or duodenal) hæmorrhage cases seen by me in the last two or three years, of which three were not operated upon and in which the patients died, while all the three patients operated on recovered.

Necropsy.—The organs of the head and chest were normal, except the lungs, which were slightly congested at the base, and the bronchi were rather catarrhal. Examination of the abdomen showed that the intestines were healthy and there was no general peritonitis. The gastric wounds were healthy-looking. There was no leakage. The left lobe of the liver was perforated one and a half inches above and slightly to the left of the notch. The liver otherwise was normal. The whole of the omentum was gathered up into a thick bunch, matted closely to the greater curvature and adjacent to part of the anterior wall of the stomach and adherent at the ends, also to the liver and the spleen respectively. The transverse colon was drawn up close to the lower border of the matted omentum. In the interior of this bunched omentum and in a small cavity of the size of a florin, apparently formed by the adhesion of the omentum to the stomach, was a thin layer of greenish purulent lymph. All the other organs and regions of the abdomen were normal. The slough in the right heel extended down to the bone. (The notes are by Mr. H. H. Stiff.)

CASE 12. *Five years' history of gastric troubles; repeated treatment by rest and rectal feeding followed by relapses; subphrenic abscess drained and cured; slight attacks of hæmatemesis frequently repeated; very depressed condition; gastro-jejunostomy; death.*—The patient, an unmarried woman, aged 28 years, unhealthy and depressed-looking, anæmic, and with much acne on the face, was admitted on Feb. 18th, under the care of a medical colleague, suffering from tenderness in the epigastrium. There was a long history (five years) of pain immediately after food which was relieved by vomiting. Three years previously an abscess appeared below the lower border of the ribs on the left side, and it was drained with tubes in the Windsor Hospital. The patient had been several times subjected in hospital to a six-weeks' course of rectal feeding (once to an eight-weeks' course). On each occasion she was relieved for from seven to nine months. She had vomited blood first six weeks previously and six times since, on one occasion half a pint. There was habitual constipation. The periods were scanty and irregular. She was now fed (per rectum chiefly) for 37 days on peptonised milk, beef-tea, barley-water, and occasionally a little brandy and soda-water, also a quarter of a grain of opium three times a day. During all this time she vomited nearly every day, often several times; one day 10 times. The vomit was, as a rule, blood-stained. There was a good deal of pain. The temperature was usually normal; once it went up to 100° F. About 10 days before the end of this period I was asked to see her; but I felt reluctant to operate owing to the depressed and unhealthy-looking appearance of the patient which differed considerably from the aspect of a person suffering only from gastric ulcer and its usual consequences. However, on March 27th it seemed that something surgical must be done, as the patient continued to be in pain and to vomit daily as much as ever.

Operation.—An anterior gastro-jejunostomy was performed. The note says: "Stomach small. Veins were varicose or dilated as if some portal obstruction. No ulcer or thickening or adhesion felt." On opening the abdomen I found the transverse colon distended with solid fæces in large lumps to such a degree as to prove to be a mechanical obstruction to the proceedings of the operation and possibly afterwards to the passage of the contents of the jejunum when a loop of that bowel was brought over and fixed to the stomach.[1] And, further, contrary to my usual custom, I sutured the mucous membrane of the stomach to that of the intestine with a continuous (glover's) suture. To these two factors (one or both) I am inclined to attribute the unfortunate course of the case—vomiting for two days followed by collapse and death.

Post-mortem examination.—An abscess was found between the layers of the stomach wall (an "intramural abscess") around the gastro-enterostomy wound, and spreading from the same centre a localised, adhesive, but probably septic peritonitis in the adjacent part of the abdomen. The anastomosis is vividly described as "looking tight and admirable." The entire colon was full of dry formed fæces—packed. The sequence of events was, I think, as follows. The gastro-enterostomy wound was, like all or nearly all other gastro-enterostomy wounds, not absolutely aseptic, because the stomach cannot be perfectly asepticised. But the close glover's suture of the mucous membrane prevented it from draining either into the stomach or the intestine. A collection of bloody serum formed in the stomach wall. Matters were aggravated by the want of rest caused by the constant vomiting and the vomiting itself was kept up by the suppuration, and possibly also by mechanical obstruction of the jejunum due to the colon being distended with fæces. No ulcer was found post mortem in spite of a careful search by several observers. Perhaps free purging and even a colotomy would have done this patient more good, not only than gastro-enterostomy but also than opium and rectal feeding. (The notes are by Dr. M. V. Dee.)

---

[1] The entire colon and rectum were found to be packed with fæces post mortem.

CASE 13 *Severe recurrent hæmatemesis; gastro enterostomy with Murphy's button; recovery.*—The patient was a middle-aged woman, a patient of Dr. James Allan of Chislehurst, the subject of severe recurrent hæmatemesis. With the help of Dr. Allan and of Mr. A. S. St. John (anæsthetising) gastro-enterostomy was performed on Sept. 6th, 1901, with Murphy's button. The Murphy's button was passed per anum, and the patient writes (six months after operation): "I shall come and see you and then you will see how well I look."

CASE 14.—This was a case with an old history of gastric ulcer and of very severe hæmatemesis years before, of chronic dilatation of the stomach, and of *tetany*. Death took place before the surgeon could arrive. It was recorded briefly in THE LANCET of June 22nd, 1901, p. 1789.

CASE 15. *Five years' history of gastric trouble suggesting ulcer; repeated treatment by rest and rectal feeding; temporary benefit; relapse; gastro enterostomy; retention of the button; its removal by gastrotomy; cure up to date.*—The patient, a girl, aged 15 years, was admitted on Dec 7th, 1900 She was anæmic but was well nourished. She had first suffered from pain in the stomach five years previously. She was put to bed for one month and was kept on milk diet and she got quite well and remained so for a month Then a relapse was treated in the same way and the cure lasted for a year. She went into service one year previously to admission. After a time the abdominal pain and vomiting recurred In August, 1900, she was admitted on the medical side of the hospital and was treated for "gastric ulcer," by rectal feeding for 18 days and was discharged after another week on "half diet;" "free from all pain since the fourth day after admission." After another month's domestic service she had her first menstrual period, but her second only a week previously to admission. When admitted she appeared to be well nourished but rather anæmic. She had no appetite and the sight of food caused nausea. Pain came on in the epigastric region immediately after food and lasted for several hours. She had only once raised blood, then she also "coughed up a small clot the size of a finger-nail." Tenderness was marked at two points, both in a line drawn upwards and outwards from the umbilicus, one just under the edge of the ribs and the other midway between the ribs and the umbilicus. On liquid diet the patient lost her pain but when a fortnight after admission she was allowed solids the pain returned severely.

Operation.—The operation, which was performed on Jan. 1st, 1901, comprised a median epigastric incision and an anterior gastro-enterostomy with Murphy's button, the jejunum being opened 20 inches from its proximal end. The pylorus was thickened and was one inch to the right of the middle line. The mucous membrane of the stomach was bright-red in colour. No search was made for an ulcer except in the part of the stomach which easily presented itself. *There none could be felt from without.* The desire was to make the operation as simple and uncomplicated as possible. On Jan. 2nd during the night there was altered blood in the vomit. Sips of hot water were allowed by the mouth. From then no more vomiting occurred and after the fourth day no pain until the patient was allowed to get up on the 29th. Afterwards pain and tenderness were felt in the epigastrium. The presence of the button in the stomach was suspected. A skiagram was taken but it showed nothing Ultimately the shadow of the button was plainly seen on the screen and it was removed by gastrostomy. It was found to be still fixed in the gastro-enterostomy opening.

Removal of the button, May 7th.—An aperture was made in the anterior stomach wall and the gastric half of the button was unscrewed and taken out. The jejunal half could only be extracted by a good deal of manipulation, assisted by notching the opening. The process of extraction left the wall of the gastro-enterostomy opening so thin on one side that a few Lembert's sutures were inserted to back it up The first aperture was mostly closed by three sutures penetrating all the gastric coats and tied with the knots inside the stomach. The rest was closed by Halsted's suture. The cause of the retention of the button was probably its not having been screwed up quite tight enough. (The notes are by Mr. Stiff.)

The patient was seen recently and she described herself as feeling quite well. She looked bright though she was still rather anæmic.

Three cases of hydrochloric acid poisoning.—These cases form the subject of a paper read before the Royal Medical and Chirurgical Society and published in THE LANCET of Nov 17th, 1901, p 1328. Two were suicidal and both of the patients died, one because the case was too advanced for operation and one from progressive ulceration of the œsophagus and gangrene of the lung, about six weeks after I had performed a gastro-enterostomy, which relieved her for a time. The third patient made an admirable recovery after Loreta's operation which removed intense emaciation and other disagreeable and dangerous symptoms due to an enormously dilated stomach. I am convinced that the safety of such cases lies in very early operation combined with special treatment described in the paper referred to.

Four cases of severe gastric hæmorrhage were reported in THE LANCET of June 8th, 1901, p. 1597.

The above 22 gastric cases include all that I have been consulted on *for non-malignant gastric troubles* in the past four years. Gastric symptoms have also been present in cases in which there were adhesions of the omentum, &c., secondary to hernia, or to inflammatory affections of the gall-bladder, or of the pelvic organs. In these cases the prime disease has been treated operatively with success. Incidentally I have seen a few patients with symptoms of gastric ulcer who came to me with lateral curvature of the spine. In these spinal cases the indications for treatment of the stomach seemed to be purely medical and hygienic, combined with attention to the spinal curvature.

Correction.—In the table on page 886 (THE LANCET, March 29th), last column, opposite Case 16, for "gastrostomy" read *gastroenterostomy*.

Grosvenor-street, W

THE SUPPOSED INFECTIVITY OF DESQUAMATION IN SCARLET FEVER.[1]

BY C. KILLICK MILLARD, M.D., D.Sc. EDIN.,
MEDICAL OFFICER OF HEALTH AND MEDICAL SUPERINTENDENT OF THE BOROUGH ISOLATION HOSPITAL, LEICESTER, LATE MEDICAL SUPERINTENDENT, CITY FEVER HOSPITAL, BIRMINGHAM.

ONE of the many points in connexion with the natural history of scarlet fever calling for further investigation is the supposed infectivity of the desquamation which is so marked a feature of the disease From the point of view of fever hospital administration the question is one of the first importance, for the prolonged detention of scarlet fever patients which is still enforced in so many hospitals is largely out of deference to the prevailing belief that the presence of any trace of desquamation is evidence of continued infectivity. The view that desquamation is infectious was authoritatively endorsed by the committee appointed by the Clinical Society of London "to investigate the periods of incubation and contagiousness of certain infectious diseases." Its report was published in 1892 and in the conclusions as to scarlet fever it is stated. "(2) ...... Infection certainly persists so long as there is any desquamation and may still be active at the end of eight weeks" The evidence, however, upon which this emphatic and unqualified statement was presumably based was of the scantiest and most inconclusive description. Out of 209 cases received in evidence in connexion with scarlet fever, only three had the slightest bearing upon the question of the infectivity of desquamation. Indeed, I think I am right in saying that only in these three cases was desquamation even referred to. These cases were as follows —

CASE 24 (communicated by Dr. Murchison in 1878).—On April 1st, 1878, Master P. left school at Wimbledon, on the fortieth day of an attack of scarlatina, for his home at Brighton. Before leaving, desquamation had to all appearances quite terminated, the feet having desquamated twice. Also he had had repeated carbolic acid baths and he had left all his infected clothes behind. After reaching Brighton his face and feet desquamated again and four days after his arrival his mother fell ill with scarlet fever.

CASE 58 (communicated by Dr. Whitelegge).—B., a girl, aged 19, slept one night with a cousin who was undergoing a second desquamation on the feet eight weeks after the original attack. B. had scarlet fever rash four days subsequently.

CASE 64.—A girl desquamating after scarlet fever went to live in a household and a boy, aged five years, had scarlet fever rash five days later.

The details given in the above cases are so meagre that it is quite possible that there may have been a simple explanation of the conveyance of infection quite independent of the desquamation. It is unnecessary to assume this, however, because it is well known that infection is often carried after prolonged periods of isolation, when there is no discoverable lesion whatever. The committee itself admitted this, for it stated :—"It is, however, well shown ...... that a patient who is completely convalescent—so far, at any rate, as would appear on a cursory examination—may yet be, in some way, capable of infecting others." Whilst fully recognising the very valuable and scientific nature of this report as a whole, it is difficult to avoid thinking that the committee's "conclusion" was, in this case, rather the expression of a preconceived opinion than a genuine conclusion arrived at from the evidence examined. Whether or not, however, the committee was justified in coming to this conclusion, there can be no doubt that it was supported in the view which it took by the vast majority of the medical profession.

---

[1] Abstract of a paper read before the Epidemiological Society on Feb. 21st, 1902.

So firm is the belief that a desquamating patient is necessarily still infectious that actions at law have repeatedly been based upon it as if it were a settled fact. Parents have frequently been prosecuted by corporations and convicted; and, on the other hand, corporations have been sued by parents and mulcted in heavy damages. The most glaring example of vexatious litigation in connexion with this subject is probably that of Jameson *v.* the Metropolitan Asylums Board which occurred in 1896. In this case, according to the report which appeared in the press, a claim was made against the Metropolitan Asylums Board by the secretary of a training school for girls for £13 for expenses in consequence of one of the girls being sent back from hospital still desquamating. The expenses were incurred owing to some of the boarders having to be sent home and the whole house having to be disinfected over again. No one else contracted the disease but a general practitioner had given it as his opinion that the girl was still infectious. The facts proved in evidence were that the patient was discharged after being in hospital 16 weeks. 17 days later she was found to be desquamating on the fingers and toes and was sent again to the hospital on the following day. She was then isolated for a further period of six weeks. The judge said that it was impossible to say that there was carelessness on the part of the hospital medical officers and so gave judgment for the defendants. At the same time he refused costs on the ground that it was a proper case for inquiry. In the face of such cases as these, medical superintendents of hospitals, whatever may be their own convictions, find little encouragement to discharge patients from hospital until all trace of peeling has disappeared. Believing very strongly that this view, although long established, was not supported by experience, I sent five queries to the medical superintendents of the principal fever hospitals in the country, and to a few others whose opinion I believed would command respect—25 in all. These queries were as follows :—

1. Can you adduce any evidence, experimental, statistical, or clinical, tending to prove that desquamating epithelium is, *per se*, a source of infection? 2. Do you consider that too much importance has in the past been attached to desquamation as a source of infection? 3. Does your experience support the popular belief that desquamation after scarlet fever is necessarily an indication that a patient is still infectious? 4. Does your experience lead you to believe that a patient may continue to desquamate, especially on the feet, for some time after he has ceased to be infectious? 5. Does your experience lead you to believe that it is necessary, in order to prevent the spread of infection, that patients, who otherwise are quite ready to leave hospital, should be detained until every visible trace of desquamating epithelium has disappeared?

Of the gentlemen to whom these queries were sent the following 21 favoured me with replies. Dr. J. E. Beggs, Dr. R. A. Birdwood, Mr. R. M. Bruce, Dr. F. Foord Caiger, Dr. W. Gayton, Dr. F. N. Hume, Dr. C. E. Matthews, and Dr. F. M. Turner (all the foregoing are medical superintendents of fever hospitals belonging to the Metropolitan Asylums Board); Dr. P. Boobbyer, medical officer of health and medical superintendent of the Borough Hospital, Nottingham; Dr. J. E. A. Chatelier, medical superintendent of the City Hospital, Birmingham; Dr. E. O. Hopwood, resident medical officer at the London Fever Hospital; Dr. J. T. Kitchin, medical superintendent of the City Fever Hospital, Bradford; Dr. C. B. Ker, medical superintendent of the City Hospital, Edinburgh; Dr. J. Priestley, medical officer of health, Lambeth, formerly medical officer of health and public analyst, Leicester; Dr. H. Meredith Richards, medical officer of health, Croydon, formerly medical superintendent of the City Hospital, Birmingham; Dr. J. W. Washbourn, physician to the London Fever Hospital, &c.; Dr. Meredith Young, medical officer of health and medical superintendent of the Borough Hospital, Stockport; Dr. H. J. E. H. Williams, medical superintendent of the City Fever Hospital, Sheffield; Dr. A. Johnston, physician superintendent of the Ruchill Fever Hospital, Glasgow; Dr. H. R. Kenwood, medical officer of health, Stoke Newington; and Mr. A. E. A. Pearson, medical superintendent of the City Hospital, Leeds.

I have divided their replies into two groups: (*a*) those taking what I will call the "new" view (though I recognise, of course, that it has no real title to the designation); and (*b*) those adhering to the old view, or occupying an intermediate position. The uniformity in the answers in the former group shows, I think, that the points at issue were well appreciated. Practically all the gentlemen in that group, 16 in number, state that (1) they can adduce no evidence that desquamating epithelium is, *per se*, a source of infection; (2) they consider that too much importance has been in the past attached to desquamation as a source of infection; (3) their experience does not support the popular view that desquamation after scarlet fever is necessarily an indication that a patient is still infectious; (4) they believe that a patient may continue to desquamate for some time after he has ceased to be infectious; and (5) they do not believe that it is necessary, in order to prevent the spread of infection, that patients, who otherwise are quite ready to leave hospital, should be detained until every visible trace of desquamating epithelium has disappeared. There is much less uniformity in the answers in the latter group. They are only five in number, and one or two may almost, I think, be said to favour the new view. Judging from the answers which I have received, therefore, it is clear that a great preponderance of expert opinion is contrary to the old and popular view, and it follows that the existing practice of detaining all patients till the last trace of desquamation has disappeared could be safely modified in the direction of considerably shortening the period of isolation.

In suggesting that the desquamation of scarlet fever is not infectious I simply mean that it is not infectious *per se*. The flakes of epithelium given off by a patient still in the infectious stage may naturally be expected to carry the infection as fomites, just as the clothing worn by such a patient or other articles in contact with him would do. On this hypothesis a piece of desquamated cuticle from a scarlet fever patient if sent in a letter through the post might readily convey the disease if the patient from whom it came was still in an infectious state, but the mere presence of desquamation ceases to be any evidence that a patient is still in an infectious state. The real question at issue is, Does the desquamating epithelium contain in itself the infecting elements—i.e., the supposed germs of scarlet fever—in the same way that the scabs of small-pox are believed to do? The pustules of small-pox undoubtedly contain the specific microbes of the disease and it is only to be expected, therefore, that the scabs, the remains of the pustules, should also contain them. This provides a simple explanation of the fact that the "striking distance" of small-pox is such a long one and that its infection is so readily air-borne. In scarlet fever, however, the eruption is an erythema—a process characteristic of chemical poisoning or of poisoning by the chemical products of microbic action rather than of the direct action of microbes themselves. Thus there are erythematous rashes, closely resembling the rash of scarlet fever, after the use of certain drugs and in cases of septic absorption, and these erythemata are sometimes followed by desquamation. Desquamation, much more profuse even than that seen in scarlet fever, follows the eruption of erythema scarlatiniforme desquamativum; yet there is no reason to think that the process in any of these cases is a microbic one. I hold, therefore, that the desquamation of scarlet fever should be regarded as also a non-microbic one.

In the absence of bacteriological evidence, it appears that the only way in which this question can be settled is by specially-collected statistics. A number of cases must be sent out from hospitals still desquamating, but otherwise apparently quite free from infection, and the result compared with that of similar cases in which desquamation has been completed. In a small way I have myself attempted something of the kind, both in Birmingham and in Leicester. My object was to find out whether patients sent out desquamating were more frequently followed by "return cases." My records in Birmingham covered some 4810 cases during the two-and-a-half years 1894-96 8·0 per cent.[2] of these were noted as showing some trace of desquamation (principally late desquamation on the feet) at the time that they were discharged. But of the cases which carried out infection (by giving rise to "return cases") only 6·5 per cent. had been noted as showing traces of desquamation.

In Leicester during the three months Sept. 14th to Dec. 14th, 1901, I tried the experiment of reducing the minimum stay in hospital to four weeks. The average stay in hospital, including time ill at home, during these three months has been 39·1 days, or counting only time in hospital, 35·3 days (excluding[3] cases which were sent home on account of erroneous diagnosis). In order to obtain this result it was necessary in many cases to "pass" patients prior to completion of all desquamation. The total number of cases sent out was 190 and the number of "return cases" was five. The particulars of these "return cases" are given in the accompanying table.

A TABLE GIVING PARTICULARS OF FIVE "RETURN CASES" ARISING OUT OF 190 PATIENTS DISCHARGED AFTER AN AVERAGE ISOLATION OF 39·1 DAYS.

	Infecting case.			Return case.		
No.	Sex and age of patient.	Duration of infecting case and dates of onset and discharge.	Condition of infecting case at time of discharge* and subsequent health.	Sex and age of patient.	Date of onset of return case.	Interval between discharge of infecting case and onset of return case.
1	Male, aged four years.	41 days—August 25th to Oct. 5th.	"Looks unhealthy." After return home suffered *from constant* nasal discharge.	Male, aged eight years.	Oct. 15th.	10 days.
2	Male, aged four years.	42 days—August 28th to Oct. 9th.	Crack behind ear not healed.	Female, aged two and a half years.	" 16th.	7 "
3	Male, aged four years.	47 days—Sept. 14th to Oct. 31st.	"Nose better, but not quite right. Still desquamating on feet."	Male, aged three years.	Nov. 5th.	5 "
4	Male, aged 11 months.	26 days—Oct. 28th to Nov. 23rd.	"Nose looks suspicious; little discharge."	Male, aged seven years.	Nov. 27th.	4 "
5	Male, aged 16 years.	39 days—Oct. 26th to Dec. 4th.	"Sore nose." Sore at home after return for more than a fortnight.	Female, aged nine years.	Dec. 17th.	13 "

* As recorded on the bed chart at the time that the patient was "passed."

Note.—The subjects of the infecting cases in Nos. 1, 3, and 4, had suffered from rhinitis whilst in hospital.

In only one case was there any desquamation present in the "original" or "infecting" case: this was on the feet, and it was also noted that the patient was suffering from a sore nose, which latter fact alone is, in my experience, amply sufficient to account for the "return case."

An attempt to send patients out of hospital at the end of a month is not, in the present state of public opinion, free from difficulties. There is always, of course, the possibility that "return cases" may occur with patients sent out desquamating, just as there is with patients sent out suffering—let us say—from corns or decayed teeth; and should this happen censure is likely to follow. A medical man is called in and if he finds the least trace of peeling he frequently expresses the opinion that the patient was sent out from hospital too soon.

There is one other point which I must mention. As things are at present the public will readily believe that a patient is still infectious and will continue to take precautions as to isolation, &c., so long as desquamation continues. Shake their faith in this and patients might be running about the streets at the end of 10 days or a fortnight. I fully realise the force of this. What medical officer of health, indeed, has not found it convenient to avail himself of this firmly-established belief? As students of science, however, we ought not to allow such an opportunist consideration as this to obstruct our search after truth. Moreover, our methods and measures for controlling the spread of scarlet fever (based largely upon theories) have not been such a conspicuous success in the past that we need apprehend any very serious consequences from a little modification of them in the future.

In conclusion I may briefly sum up the principal arguments against the supposition that desquamation is infectious, as follows: 1. The absence of evidence supporting it. It is difficult to believe but that if the old supposition were correct, strong evidence of it would ere this have been forthcoming, as is now the case with discharges from the nose and ears. 2. The fact that infectivity begins prior to the onset of desquamation and frequently continues long after desquamation has ceased. 3. The fact that scarlet fever wards, although abounding in desquamating epithelium, are not a danger to neighbouring houses. 4. The fact that the proportion of "return cases" does not appear to be increased amongst patients sent out from hospital still desquamating. On the other hand, the principal argument in favour of the view that desquamation is infectious is the fact that patients still desquamating, but otherwise apparently free from infection, have frequently been known to convey the disease to others. The whole force of this argument disappears, however, when we consider that patients apparently quite free from infection and in whom desquamation has entirely ceased have also been known to convey the disease; moreover, patients still desquamating have frequently mixed freely with others without untoward result.

Leicester.

THE TOPICAL APPLICATION OF MUCIN IN CERTAIN AFFECTIONS OF THE NOSE, THROAT, AND EAR.

BY WILLIAM STUART-LOW, F.R.C.S. ENG.,
REGISTRAR TO THE CENTRAL NOSE, THROAT, AND EAR HOSPITAL.

IN communications to THE LANCET of Sept. 8th, 1900, p. 730, and Oct. 12th, 1901, p. 972, and in papers read before the British Medical Association at the last two annual meetings, I described the beneficial action of mucin when administered in cases of painful digestion, gastritis, and gastric ulcer, and I gave the history of patients from my own practice and that of others who had proved its effectiveness in the alleviation of such painful gastric conditions. In these papers I also pointed out what I think had not hitherto been observed—viz., that almost invariably these stomachic symptoms were accompanied by a more or less pale and secretionless or dry condition of the naso-pharyngeal mucous membrane; and I showed the advantages of applying mucin to the nose and throat as a part of the treatment of these gastric affections. It was also shown that the deficient mucous secretive action of these surfaces was often a persistent and long-standing antecedent of the gastric irritation and an active factor in its causation. Anatomical and physiological facts were cited to prove that normally much mucus is meant to be carried onwards to the stomach to act as a protective against attrition by lumpy food and irritation by the acid gastric juice.

---

[2] This percentage was estimated from the records of only 2000 of the cases discharged but the same system of discharging was followed throughout.

[3] There were no deaths to exclude.

The *bête noire* of nose, throat, and ear practice is the difficulty of successfully accomplishing amelioration of aridity of the mucous linings of these organs and the fact is that to such aridity all the other intractable, disagreeable, and distressful symptoms are due—namely, incrustation, fœtor, ulceration, hæmorrhage, and pain. The lessened mucous flow by causing desiccation causes also the loss of the essential and special nasal functions of smell and the filtration and warming of the inspired air. I claim for mucin that it does more than anything that has yet been tried to relieve the discomfort in mild cases and to mitigate the distress and suffering in the more severe. It is a natural remedy which restores the moisture and maintains it in virtue simply of its hygroscopic properties. I have had ample opportunities of testing the efficacy of mucin in the very extensive and mixed out-patient department of the Central Nose, Throat, and Ear Hospital.

As usual when the pathology of disease is obscure there have been much speculation and many theories put forward to explain the causation of atrophic and dry rhinitis and pharyngitis, and the treatment is, consequently, very unsatisfactory. I will not attempt to solve the pathological problem as to how the dryness and atrophy in these conditions are to be accounted for but will briefly indicate how mucin acts in *remedying them. Two researches that I had carried out by* Dr. G. L. Eastes of the Laboratory of Clinical Pathology, Queen Anne-street, W., the first two years ago and the second last year, throw much light on how mucin acts. In the first research it was conclusively shown that mucin has a retarding influence on bacterial growth, that sterilised solutions containing mucin remained sterile for a long time on exposure to the air, and that bacteria ceased to grow in culture media when mixed with mucin. This is a very interesting and important fact, as it indicates that nature has in the secretion poured out on mucous membranes provided a ready means for the suppression and retardation of growth of bacteria. In the *British Medical Journal* of March 8th last in the pathological column of recent literature (see Epitome) there is an account (quoted from the *Lyon Médical*) of a research by Professor Fernand Arloing in which this work is repeated in an investigation of the action of "mucidine"—a solution of the mucus of red snails—upon the bacillus of Löffler. From this he concludes that mucidine possesses a bactericidal action and that it retards the growth of other bacteria. The second research proved that mucin is hygroscopic in its action, being about one-fourth as absorbent for water as glycerine is, and that in this way it will act as a moistening agent—gently, slowly, and with lasting effect. According to this investigation 100 parts of mucin absorbed 3·8 parts of water in four hours, while 100 parts of glycerine absorbed 16·3 parts of water in the same time.

When applied locally to the interior of the nose and pharynx mucin has a soothing and emollient action; it moistens the surface and softens incrustations, readily facilitates their removal and prevents their re-formation; it thus also obviates fœtor, which is one of the best points in its favour as a local remedy. Mucin also restores the nasal function of smell by its hygroscopic effect and the filtration and warming functions are also resumed, because in a dry condition the mucous membrane is functionless. Messrs. Burroughs, Wellcome, and Co. have prepared for me a soloid composed of five grains of mucin, five grains of sodium bicarbonate, and one grain of menthol. This is prepared for use by dissolving it in one ounce of sterilised warm water, or, more thoroughly to get more of the mucin into solution I am in the habit of dissolving the soloid in equal parts of sterilised warm water and sterilised warm lime water. This solution may be used to spray, to douche, or to syringe the nose and throat twice daily. The spray should be a coarse one, as otherwise it is liable to get clogged with particles of undissolved mucin. A very good plan to obviate this is to spray warm water at least once a day through the instrument and thus wash it out. If much incrustation has to be got rid of it is well to rub it off with cotton-wool saturated in the warm mucin solution on a mounted prop. In severe and very old-standing cases of atrophic trouble I supplement the local treatment by giving the patient tabloid mucin co. containing five grains each of mucin and sodium bicarbonate internally before and after meals and thus relieve the concomitant gastric irritation and constipation.

I have had very good results in the treatment of dry conditions of the larynx and in cases where there have been incrustations on the laryngeal lining from the use of a spray of warm soloid mucin solution, the discomfort and hoarseness very soon being much relieved. I have at present 10 cases of dry catarrh of the middle-ear with narrowing of the Eustachian tubes and varying degrees of tinnitus and deafness under treatment. I am injecting twice a week a few drops of a solution of the soloid mucin co. of the same strength—1 in 1 ounce of sterilised warm water—into the Eustachian tubes. While the constant and terrible tinnitus of some of these patients has certainly been much relieved—and in some instances this has existed for years and proved quite unamenable to every form and variety of remedy—and the hearing has also improved, I can speak only tentatively of my results as I have not had the cases regarding which I write long enough under observation. The results, however, are distinctly encouraging, especially as the narrowing of the Eustachian tubes has become less evident. Where patients are very sensitive to the solution of the soloid of the usual strength (1 in 1 ounce) I either dilute the solution more or substitute for the soloid the tabloid for internal use. This has no menthol in its composition but I prefer the soloid, as the menthol serves to stimulate the remaining unatrophied mucous glands to secrete.

The substance most generally used at present for intra-Eustachian injection and as a nasal spray in these affections is a liquid oily paraffin with menthol in the proportion of *two and a half grains to the fluid ounce. I object entirely* to liquid grease in any shape or form for softening and moistening purposes. It is certainly absolutely useless as a moistening agent; indeed, such preparations act inimically, because they clog and paint over the still remaining and half-atrophied mucous glands. Such oily substances should never be thought of for the purposes of relieving a similarly dry condition of the oral cavity and yet they are commonly persisted with in the treatment of nose and throat and ear cases. What is required is a warm alkaline watery solution of mucin as a substitute for the deficient natural secretion and this is just what the solution of the soloid mucin co. supplies. The more potent penetrating effect of the watery solution is proved by the fact that menthol when used to the amount of only one grain to the ounce of the mucin solution is, by some patients, felt to be quite pungent enough in its stimulating action, as compared with the solution of menthol in liquid oily paraffin, in which it can be borne even to five times the strength.

I have found that even long-standing cases of atrophic nasal and pharyngeal trouble do very well, and that the crusts soon cease to accumulate, after regular douching twice daily with solution of soloid mucin co., and that no other irrigations are ordinarily necessary; but there are certainly instances when pus is present in the discharge in which it is advantageous to use just before the mucin douche a lotion of sodium sulphate or a combination of sodium sulphate and bicarbonate for cleansing purposes. I have patients who, after years of suffering from typical atrophic rhinitis with all its horrors of fœtor and discomfort have, after continuous and persistent application of the mucin irrigation, now been able to dispense with treatment to a greater extent than two or three times weekly.

Welbeck-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF GANGRENE OF BOTH NIPPLES OCCURRING IN THE PUERPERIUM.

By RALPH VINCENT, M.D., B.S. DURH.,
M.R.C.P. LOND.,
LATE SENIOR RESIDENT MEDICAL OFFICER, QUEEN CHARLOTTE'S LYING-IN HOSPITAL.

GANGRENE of both nipples occurring in the puerperium is an extremely rare accident. So far as I am aware there is no recorded case at all similar to the one which I am about to describe and I therefore think that it should be published. For permission to report the case I am indebted to Dr. W. S. A. Griffith.

The patient, a single primigravida, aged 23 years, was delivered at Queen Charlotte's Lying-in Hospital on June 3rd.

On the 7th (the fifth day) both nipples were excoriated; they were protected by rubber nipple-shields and were thoroughly dusted with orthoform, which treatment was continued for some days. On the 15th (the thirteenth day) the whole of the front of the chest over the breasts was covered with a dark red rash, uniform in character and papular at the edges. The skin was apparently infiltrated and thickened, slightly œdematous, and very tender; both nipples were excoriated. The patient complained of severe burning pain in the region of the rash and of headache. At this time the question of erysipelas was raised; the general character of the eruption was not altogether unlike that of erysipelas and the spreading margin was suggestive; but with such an extensive attack the patient must have been very ill. As it was she complained of little but headache and the local pain; her general condition was good and quite excluded erysipelas; the temperature was 100·6° F. The infant was taken from the breast and was fed artificially, the milk being withdrawn whenever necessary by the breast-exhauster. The breasts were then bathed with lead lotion. On the 17th (the fifteenth day) the appearance of the skin had not altered but the patient complained of great irritation and the temperature was much higher, being 103·4° at 4 P.M. On the 18th pustules had formed over the whole of the chest and the rash was spreading to the back. On the 19th the nipples were greyish-black and the left one was insensitive; the patient stating that she had "no feeling in it." On the 20th the rash was fading and the itching was less. The patient slept after an injection of morphia. The bases of the nipples were tender and the nipples were black and inclined to bleed. The rash had extended to the buttocks. On the 21st the nipples were definitely gangrenous, the line of demarcation being around the areolæ. The rash on the chest was now much faded, but there were red blotches on the face, chiefly about the nose, the chin, and the forehead. On the 22nd this rash on the face was less and the left nipple had separated, leaving a red granulating surface of about the size of a shilling. The right nipple was sloughing and had nearly separated. On the 23rd the right nipple separated, leaving a similar granulating surface. The rash on the chest had now quite disappeared and the epidermis was desquamating in small flakes; there were still a few blotches on the face. From the granulating surfaces left by the separated nipples pus was discharging freely. On pressing the breasts milk exuded from the openings of the milk-ducts at the base of the ulcers. The progress of healing was uninterrupted and the further history of the case was quite uneventful. The patient left the hospital on July 12th with the ulcers almost completely healed, and on the 18th, when she attended the hospital, they were quite healed. It is an interesting and important feature of the case that notwithstanding the complete destruction of both nipples there appeared to be no obliteration or occlusion of the milk-ducts, so that in the event of a future pregnancy lactation would probably be normal and suckling would be possible by the use of a shield to take the place of the destroyed nipples.

It is impossible to prove the cause of the gangrene, but I suspect that the primary cause was orthoform. A rash has followed the use of this preparation and is, I understand, well known to those who use orthoform in general surgery. Gangrene of the nipples is so unique an accident that one must regard any unusual feature in the case with suspicion. The only unusual feature was the use of orthoform.

Harley street, W.

A CASE OF SPINA BIFIDA IN A MARRIED WOMAN, AGED 27 YEARS; RUPTURE; OPERATION WITH SUCCESSFUL RESULT.

BY F. FAULDER WHITE, F.R.C.S. ENG., L.R.C.P. LOND.,
HONORARY SURGEON, COVENTRY AND WARWICKSHIRE HOSPITAL.

THE patient was admitted to the Coventry Hospital on Jan. 30th suffering from a large swelling over the sacrum, in the centre of which was a dark spot from which oozed a thin fluid. The history of the case, briefly, was that until a few weeks previously the tumour had given little trouble—the patient had even given birth to a child; but from the time that the skin gave way there had been much headache and pain in the thighs. Mr. J. L. Callaghan who was attending the case tried several means to prevent the loss of cerebro-spinal fluid but in vain, and it was decided in consultation to give the woman the chance of cure by operation. On Feb. 2nd I operated. The tumour was of about the size of a large child's head at birth, full of fluid and covered by a very thin skin. Making an elliptical incision I excised about two-thirds of the skin covering the swelling and dissected out the sac. The sacral wall was found to be deficient for about three inches over the spinal canal, there being absolutely no bony covering in this region. No large nerves were found in the sac, most of which was removed. The cut edges of the sac were sewn together and some trouble was taken to draw the tissues over the spinal cavity. The patient suffered at first from great pain in the legs and back. After a few days oozing occurred through some deep stitch-holes. At this time headache was severe. This oozing was undoubtedly of spinal fluid, but after three or four weeks it ceased and the stitch-holes filled up. There is now no trouble of any kind and the wound has consolidated. The patient is up and has lost all pain. She expresses much satisfaction at being rid of a great encumbrance.

Coventry

ANTI-STREPTOCOCCIC SERUM IN PUERPERAL FEVER.

BY MONTAGUE D. MAKUNA, M.R.C.S. ENG., L.R.C.P. LOND.

As the cases of puerperal fever treated with anti-streptococcic serum which have been recorded are few and far between, I take the liberty to relate in THE LANCET a case which has recently been under my care as it may encourage others to adopt the treatment. The patient, aged 28 years, was in her fourth confinement. She came under observation on Feb. 15th, 1902, the eighth day of confinement. The labour was easy and was attended by a "Gamp" who was probably the source of infection, as she had been attending puerperal patients a little time before. The patient was in a state of prostration, the pulse was quick, of small volume, and it numbered 132 per minute, and the temperature was 104·6° F. in the evening. The lochial discharge was scanty. There were considerable tenderness and some swelling in the right iliac region and over the pubes. The midwife's attendance was at once discontinued and the patient was enjoined to rest in bed and thorough cleanliness of the bed-linen and surroundings was insisted on. A vaginal douche of perchloride of mercury was used every day till recovery. She was given quinine, ergot, dilute hydrobromic acid, and digitalis, in a mixture. The diet consisted of milk, custards, and Mosquera beef jelly, but no stimulants were given. On the next day at noon the temperature was 103·4° and on the following day it was 102·4°, continuing between 102° and 101° till the 23rd. The tenderness in the lower part of the abdomen remained the same and she passed opalescent shreds with each vaginal douche. The case appeared to be a protracted one, as I have seen cases last for from 12 to 16 weeks when the patients recovered. As I am not favourably impressed with intra-uterine irrigation and have seen some harm done by it I did not attempt it, and I know that curettage is positively dangerous. On the 23rd I injected 10 cubic centimetres of anti-streptococcic serum (Messrs. Parke, Davis, and Co.) in the right gluteal region. On the following day the temperature fell to 100°, when another 10 cubic centimetres of the serum were injected. On the 25th the temperature was 99·4°. Vaginal irrigation brought out some lumpy shreds and purulent discharge. The tenderness over the right iliac region was much less. Another injection of 10 cubic centimetres of serum was given. On the 27th the temperature was 99° and 10 cubic centimetres of the serum were injected. On the 28th she passed a copious bloody discharge and some fœtid clots, giving her a grateful sense of relief. The vaginal irrigation was discontinued till the menstrual flow ceased on March 3rd. As the temperature on the last date was still a little above the normal a fifth injection of 10 cubic centimetres of the serum was given. On the 5th the temperature was normal and did not rise again. All tenderness passed away. She was given hypophosphites and a change was made in the diet. On March 24th she was in her usual health. All the injections were made in the gluteal regions, first on one side and then on the other, and were not followed by any after-effects locally or constitutionally. It is possible that the patient might have recovered without the serum treatment but the disease was certainly cut short by several weeks.

Treherbert.

NOTE ON THE RESULTS OF ANTI-TYPHOID INOCULATION IN THE CASE OF THE FIFTH BATTALION MANCHESTER REGIMENT IN SOUTH AFRICA.

BY A. E. WRIGHT, M.D. DUB.,
PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY.

IN view of the dearth of statistics bearing on the incidence of typhoid fever in South Africa in inoculated and uninoculated soldiers respectively the following, for which I am indebted to Lieutenant J. W. West, R.A.M.C., Winburg, Orange River Colony, may not be entirely without interest. The statistics here in question give the results obtained in the case of the 5th Battalion Manchester Regiment for the six months which have elapsed since their landing in South Africa. The figures, which relate to a total strength of 747 men and officers under observation, are as follows :—

—	Number.	Cases of typhoid fever.		Deaths from typhoid fever.		Case-mortality.
		Number.	Percentage.	Number.	Percentage.	
Uninoculated ...	547	23	4·2	7	1·3	1 in 3·3
Inoculated ...	200	3	1·5	0	—	0 in 3

The three attacks in the inoculated are reported to have been of an exceptionally mild type, contrasting in a striking manner with the severe attacks which occurred in the uninoculated. At the time of sending in the report some of the uninoculated patients were "not yet out of danger."

ROYAL PORTSMOUTH HOSPITAL.

A CASE OF TRAUMATIC DISLOCATION OF THE HIP IN A BOY AGED SIX YEARS.

(Under the care of Dr. A. LLOYD OWEN.)

THE rarity of traumatic dislocation of the hip in the young is chiefly attributable to the weakness of the femur as compared with the ligaments of the hip-joint, so that the femur gives way much more readily. It has, however, been seen even in the young, and Erichsen[1] mentions that two cases occurred in his practice; in one the bone was dislocated on to the pubes in a child 18 months old and in the other on to the dorsum ilii in a boy, aged six years. The valuable researches of Bigelow, and still more recently those of Allis, into the methods of production and reduction of this dislocation have thrown much light on the subject. It is interesting to note that even in the time of Hippocrates flexion was considered of importance in the reduction of dislocations of the hip. For the notes of the case we are indebted to Mr. F. P. Connor, late junior house surgeon.

The patient, a boy, aged six years, was admitted into the casualty department of the Royal Portsmouth Hospital on Dec. 23rd, 1901, with the following history: he was kicking a ball in the street with some other boys when suddenly both his feet slipped and he fell heavily to the ground in a position of complete abduction of both legs. He was unable to get up and complained of great pain and he was carried to the hospital. On admission he was found to be a healthy, well-built lad, evidently in great pain. The right thigh was held in a position of partial flexion and adduction and was rotated inwards. The leg was completely flexed on the thigh and was retained in that position by the patient grasping the right ankle with his right hand. The leg was straightened without much pain and the limb was seen to be in the characteristic position of a dorsal dislocation of the hip—viz., flexion and adduction at the hip and rotation inwards of the whole limb. The great trochanter was well above Nélaton's line and the head of the femur was felt distinctly rolling beneath the gluteal muscles on rotating the limb; its position corresponded to the dorsum ilii. Chloroform was administered and reduction was attempted in the usual way, the leg being flexed on the thigh, the latter on the abdomen, and then the limb circumducted outwards and brought down into a position of complete extension. It proved successful on the first attempt and the limb was put up in a long Liston's splint and the boy was admitted into the children's ward under the care of Dr. Lloyd Owen. The patient was kept in bed for a fortnight and then passive movement was carried out; he was quite well at the end of another week. He left the hospital without any shortening, lameness, or impairment of movement.

Remarks by Mr. CONNOR.—Traumatic dislocation of the hip in a child is an accident of sufficient rarity to make the above case of interest. I am able to report the case through the courtesy of Dr. Lloyd Owen.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Surgical Treatment of Obstruction in the Common Bile-duct.

A MEETING of this society was held on March 25th, Mr. ALFRED WILLETT, the President, being in the chair.

Mr. A. W. MAYO ROBSON (Leeds) communicated a paper which was read in his absence by the Secretary, entitled "The Surgical Treatment of Obstruction in the Common Bile-duct by Concretions, with especial reference to the Operation of Choledochotomy as modified by the author, illustrated by 60 cases." This paper will be published *in extenso* in a future issue of THE LANCET.

Sir DYCE DUCKWORTH remarked that as a physician he recognised the value of surgical treatment in such cases. Formerly many drugs had a traditional value for the solution or expulsion of gall-stones but he never knew any such methods to be of use. An accurate diagnosis was of very great importance. The symptom of pain did not necessarily mean obstruction. The gall-bladder was only occasionally palpable and they must not wait for this evidence before operation. Physicians could do something to prevent the formation of gall-stones. They were common in persons who were the subjects of the arthritic diathesis. But immediately gall-stones were recognised in the bladder or duct surgical aid should be summoned.

Mr. RICKMAN J. GODLEE congratulated Mr. Mayo Robson on the success of his cases, at the same time regretting his unavoidable absence. He would have liked to ask him concerning the length of the incision. The propriety of joining the gall-bladder to the colon instead of the duodenum was also another question. What was the "scoop" Mr. Mayo Robson referred to? Mr. Godlee then narrated four cases of jaundiced patients in whom bleeding occurred in spite of the fact that calcium chloride was administered. It was the characteristic generalised oozing and in two of these cases the patients died. He wished to emphasise the very septic nature of the material within the common bile-duct and the care which was required to prevent its escape.

Dr. J. H. KEAY congratulated Mr. Mayo Robson on having reduced his percentage mortality but took exception to the statement that nothing could be done by medicinal and general methods, quoting a case in point. Was not oil of any use for the solution of gall-stones? An important question was, How long was it proper to wait after a patient became jaundiced before operating? It would be interesting to know the subsequent history of Mr. Mayo Robson's cases, the records of which only extended to about 12 months, for recurrence was common.

---

[1] The Science and Art of Surgery, ninth edition, vol. i., p. 692.

Sir Dyce Duckworth stated that he had made many experiments but had never found that olive oil had the least solvent effect upon gall-stones. Referring to the question as to the indications for operation the temperature was a most important guide. This rose in cases of impaction and such cases should be operated upon promptly; and this procedure was rendered all the more imperative when it was remembered that gall-stones were frequently a determining cause of cancer starting in the biliary passages.

Dr. H. A. Caley asked why it was necessary to give such heroic doses of calcium chloride. They were apt, as Professor A. E Wright had shown, to frustrate the object in view, for they diminished, instead of increasing, the coagulability of the blood.

Mr A. C. Butler-Smythe remarked that the length of the incision was a very important point and he doubted if an operation of this character could be completed in 30 minutes. The doses of strychnine used seemed to him to be rather large.

Mr. H. J. Paterson believed that septic peritonitis was the chief source of danger and he congratulated Mr. Mayo Robson on his avoidance of this complication. It was not apparent from Mr. Mayo Robson's statements that calcium chloride was of much use, but packing with hamamelis had undoubtedly aided in lessening the tendency to hæmorrhage. Some northern physicians seemed to have been educated up to seek surgical aid at an early stage of the disease. He regarded the phrase "the shock of deep anæsthesia" as a fallacy, for the deeper the anæsthesia the less the shock. Ether was *not the most suitable* anæsthetic for abdominal sections; he reckoned that it resulted in an extra mortality of some 5 per cent. He confirmed the value of strychnine administered hypodermically before and after the operation and referred to a patient who had 40 minims injected in the course of a few hours with benefit.

The President regretted Mr. Mayo Robson's absence He would have liked to ask in how many cases had the diagnosis of stone in the common duct, which had previously been made, been found to be correct or incorrect? And, again, in how many cases had there been found at the operation some cause for the jaundice other than gall stones? He (Mr. Willett) had met with cases presenting all the symptoms of stone in which no stone was found. He had also had cases resembling cancer in which he had found a calculus, and he mentioned the case of a man who wasted from 14 to eight stones in weight.

EPIDEMIOLOGICAL SOCIETY.

Infantile Mortality in the Tropics.

A meeting of this society was held on March 21st, Mr. Shirley F. Murphy being in the chair.

Dr C. W. Daniels read a paper on Infantile Mortality in the Tropics. He did not, he said, propose to consider the causes of that among the children of Europeans but that of the native races, which had hitherto attracted little, if any, attention, though at the present time, when the resources of tropical regions were being developed by European enterprise, the decrease of the native populations and the consequent scarcity of labour acquired especially in Africa the magnitude of an Imperial question. Unfortunately, accurate statistics were not available, but it appeared that in India the deaths in the first year of life varied from 439 per 1000 births in the Central Provinces downwards, but in few districts were they much below 200. In Penang they averaged one-third of the births; in Fiji they formed 35 per cent. of those at all ages; in Freetown in 1897 and 1898 they were 408·8 and 375·7 per 1000; and the deaths under five years of age were 35·67 per cent. of the total; while in Lagos and Sierra Leone the high infantile mortality had already attracted the attention of the authorities. In British Guiana the Registrar General, Mr. E. A. G. Dalton, showed that the mortality in the first year of life differed among the several races, having been in the year 1894 for Negroes 205, for Europeans 184, and for Indians 155 only. Then 470 negro women had borne 1500 children, of whom 4·91 per cent. had died within the first week, doubtless from the deficient vitality, to which must be ascribed the 20·4 per cent. of stillbirths in the maternity practice of Georgetown Hospital which included all kinds of cases, the majority being normal labours in multiparæ. A high mortality occurred in Guiana about the eighth and ninth days from trismus neonatorum. In Freetown, Sierra Leone, 9·1 per cent. of the children born alive died the same day and 17·6 within the first week. Here, as in Guiana, the number of still births certified as such was certainly below the truth and the very imperfect certification of the causes of infantile deaths rendered the registers useless In British Guiana children were largely fed on farinaceous paps and this would account for many deaths, though severe forms of diarrhœa were seldom seen. Diseases of the respiratory organs were rare, small-pox and scarlet fever were unknown, diphtheria was very rare, and measles and whooping-cough were extremely mild. Malarial fevers, however, were a fairly frequent cause of death after the sixth month, and even earlier, a common form being the pernicious cerebral attack, rapidly fatal, with convulsions and coma. If quinine were energetically used speedy recovery followed, but many patients died within two or three hours after admission. The classical symptoms were absent, and if the cause of the convulsions was not recognised the majority of the patients died. Of 1471 deaths under one year of age 158 were from convulsions, which up to the sixth year were largely due to malaria, and in older children malarial affections were attended with coma without convulsions. In Barbados, on the other hand, where there was no malaria, though in consequence of the extreme density of the population, 1096 to the square mile, the negroes emigrated to other West Indian islands, and one-fifth of those in British Guiana were natives of Barbados, the population had increased 6·3 per cent. in 10 years. In India the question of infant mortality was complicated by small pox, cholera, and famine, but the large proportion of enlarged spleens in persons of all ages dying from other diseases indicated the frequency of malarial fever in early life. In British Central Africa there were no available statistics and epidemics of small-pox occurring every five or six years caused a heavy mortality among children, inoculation being largely practised on adults; but inquiries showed that of 552 children 2·7 per cent. died on the first day; in a very malarious district over 50 per cent., and in one much less so 38 per cent. died before puberty, while enlarged spleens were very frequent. As to the fertility of women in tropical countries it appeared that in Central Africa and in British Guiana the average number of children born alive was five, and the birth-rate among the negroes in Guiana was from 30 to 35, but this did not prevent the decrease of the population. In India that in the Punjab was as high as 43·9, but in Bengal, where it was only 32·81, the deaths exceeded the births by 2·07 per 1000 In Central Africa European administration had reduced the deaths from violence and had abolished the slave trade, but the aggregation of natives on engineering works and from the partial adoption of European modes of living had led to an increase in tuberculosis and syphilis, so that the population showed a general tendency to decrease To ensure a permanent supply of labour in the Tropics a steady increase of the native population was a necessity, for which the importation of labourers from other districts was but a temporary substitute.

Dr. H. Franklin Parsons remarked that, owing to the aggregation of the population in towns and the growing neglect of breast-feeding, the infant mortality in this country showed no signs of decreasing and the same causes might be at work among the semi-Europeanised native races.

Dr C. F. Harford-Battersby said that Dr. Daniels had not mentioned infanticide which was very prevalent in Nigeria, where not only all deformed infants but twins and such as cut their teeth in a certain order were crammed into earthen pots and exposed to die; others were poisoned, as probably they were in Sierra Leone where open violence would be punished. In the absence of breast milk the natives never gave that of cows or goats but a pap made of maize, and the usual treatment of any febrile attack was to sweat the child before a large fire and then lay it out in the open air to cool; the fertility of the women was low, though the families of the more civilised were larger.

Dr. Percy E. Adams considered that as to errors of diet matters were worse than in Europe; he had found cow's milk of the greatest value in the famine camps, but that of the buffalo which only was procurable in many parts of India was very ill-digested, probably on account of the high melting-point of the fat.

Dr. H. T. **BULSTRODE** said that he would like to know the procedure of the native midwives and whether the savage or the semi-civilised negroes were the more fertile and the more cleanly. [Dr. **HARFORD-BATTERSBY**: The former.] The paucity or utter want of available statistics was palpable at every turn, and the creation of an Imperial Board of Health on the lines of that at Berlin, which had already done good work in connexion with the health of colonists and natives in East and West Africa, was becoming yearly more necessary for the prosperity of the empire.

After some remarks by Mr. **SHIRLEY MURPHY**,

Dr. **DANIELS** replied that whatever might be the case in West Africa the prevalence of infanticide elsewhere had been greatly exaggerated. Livingstone denied its existence around the Zambesi and he had not noticed it in East Central Africa. Twins, indeed, were deemed unlucky, but there was a larger proportion of them than would have been found in Europe among the children brought to be vaccinated, not only those of Christian parents, but of others outside the influence of the mission. The influx of money was not conducive to fertility, for when a man by acquiring our language obtained higher wages he (if he did not adopt our religion) took to himself more wives. Life was easy and labour light; there were few zymotics and yet the infant mortality was high. As to India, he could emphatically deny the alleged practice of female infanticide. In Bengal there were 106 male to 100 female births, but the deaths per 1000 were in the first year 234·38 for males and 191·25 for females, and for those under five years 47·9 and 41·9 respectively.

CHELSEA CLINICAL SOCIETY.

Discussion on the Nature, Origin, and General Principles of Treatment of Cancer.

THE adjourned clinical debate of this society was concluded at the Jenner Institute of Preventive Medicine, Chelsea-gardens, S.W., on March 25th, Dr. C. A. **MORRIS**, C.V.O., the President, being in the chair.

Mr. **D'ARCY POWER** said that at the beginning of his work he had concerned himself largely with microscopic appearances because, like many other observers, he had hoped to find the cause of cancer in this manner. He was now rather inclined to despair of this method of investigation. So many histologists had found so many different appearances that the sole result of their work seemed to lie in a better knowledge of the minute appearances of epithelial cells in various stages of degeneration and a more perfect information about certain fungi which though no doubt of value had not brought them any nearer to the problems to be solved. He had therefore directed his attention of late to ascertain whether there might not be an intermediate host to convey the cancer germ, should there be one, from an extrinsic source to the predisposed human beings. There were certain districts in which cancer was more prevalent than in others and these districts lay in a well-wooded country where there were stagnant ponds or sluggish streams. The water-supply did not convey cancer, for it had happened that when two houses had used one well one house had been free from cancer whilst the other had been inhabited by a succession of persons not related to each other who had successively died from cancer. He (Mr. Power) had recently turned his attention to flies as transmitters of disease. Dr. Howard Tooth in his book on his experiences of the war entitled "A Civilian War Hospital" (p. 73) said that it was impossible not to regard flies as most important factors in the dissemination of enteric fever. The flies seemed to have a special attraction for enteric fever patients, so that in a tent full of men all apparently equally ill it was almost possible to pick out the cases of enteric fever by the masses of flies which they attracted. Flies, too, were a known cause of cholera and it had been proved that they were capable of carrying tubercle bacilli on their feet and of voiding them in their excreta. He (Mr. Power) therefore urged the hypothesis that flies might be capable of carrying cancer. If they did so their bodies should contain something tangible and perhaps comparable to some of the many cancer bodies described by different observers. The fly, too, should be able to inoculate. To settle one part of this question was not difficult: so far as the ordinary house-fly was concerned the answer was in the negative. He had devoted some time in making himself familiar with the minute histological appearances met with in the ordinary London house-fly in the autumn. He had also cut sections in the same way of some flies that had been sent to him from a house where there had been an unusual succession of cancer cases during the last three or four years. He had found in them nothing but what was already known and the results of his observations would, he hoped, shortly appear in an illustrated contribution to the *Edinburgh Medical Journal*. The second part of the problem still awaited solution. The ordinary house-fly could not inoculate directly, for its mouth parts were only capable of sipping, yet it was an every-day experience that flies did bite and that they bit more in the later summer months than in the spring, and that the fly which bit looked like a house-fly. The bite was a true bite, for it raised a small papule, though in healthy persons it usually caused no reaction. During the last year Mr. Power had treated three patients for carbuncle who attributed their condition to the bite of a house-fly. He had applied for information to Dr. B. T. Lowne who pointed out that there were two kinds of house-flies, the common house-fly and the stomoxys, the house-fly having harmless mouth parts and the stomoxys being armed with a complete set of lancets. The house-fly was a little the larger and held its head downwards when at rest; the stomoxys had three interrupted whitish stripes on its back and held its head erect. He asked those present who were interested in the question to notice whether it was the stomoxys or the house-fly which abounded where cancer was unduly prevalent, to ascertain from their cancer patients whether they could recollect being nipped by a fly, and, lastly, whether they would send him living specimens of stomoxys from cancer houses that he might have them examined microscopically.

Dr. H. R. **GAYLORD** and Mr. C. H. **ZINK**, D.V.S., of the New York State Cancer Laboratory, University of Buffalo, communicated a short note on the Presence of Cancer in Swine, which was illustrated by some microscopical slides. They concluded that it was probable that in old hogs a still greater frequency of malignant tumours might be noted than the proportion which they had found of four tumours among 2000 hogs which included many young animals. They stated that the results of their investigation seemed to be sufficient to show that malignant tumours in swine were not as rare as had been supposed previously.

Dr. R. T. **HEWLETT** said that the increased use of meat which Sir W. M. Banks considered was coincident with the increase in cancer might resolve itself into a question of over-nutrition, an intake of food in excess of that required for the repair of the natural physiological waste. Such an excessive intake might well be supposed in certain cases to lead to over-stimulation of cells with consequent excessive proliferation, especially in parts in which the cells had been to a certain extent damaged and their normal physiological activities consequently impaired. It would, he said, be interesting to know whether the affluent suffered from the incidence of cancer to a greater extent than did the indigent. If salt were the cause of the development of cancer then sailors of all people should suffer largely from the disease, for they consumed salt pork almost daily and breathed and swallowed salt in the air and spray continually. But the comparative cancer mortality figure for merchant seamen was 60 per 1000 and for fishermen it was 46 per 1000, and those figures did not support the salt diet theory. Concerning the influence of irritation as a cause of cancer it could hardly be doubted that of all places where it might be expected that cancer would occur the udder of the cow would be the most likely, yet it seemed to be unknown in that position. In regard to the nature and origin of malignant disease he pointed out that the metastases which were the dominant characteristics of carcinoma were completely simulated by the metastases which occurred occasionally in chondromata and lipomata. The parasitic theory of the nature of carcinoma was a fascinating one but to his mind it was very far from proved at the present time. Many of the Ruffer's bodies, which were at one time considered to be parasitic organisms, were, he believed, now generally regarded as being of the nature of vacuoles. The reports of the cultivation of the parasite and of the production of cancer experimentally with the pure cultures seemed to him to be unsatisfactory and inconclusive. It was very likely that the parasite producing carcinoma in man, if there was one, was different from that producing carcinoma in a rat for example, and that therefore the parasite producing carcinoma in man, although actually cultivated, would very probably fail to produce carcinoma in a rat. From the fact that carcinoma could not be inoculated from animals of a different species it was highly improbable that cultures if obtained would produce the disease except in animals of the same species as that from which it was obtained. To his mind the parasitic theory of cancer was not proven, but no one would welcome it more gladly than he should the requisite proof be forthcoming. He could not help feeling that there was more hope of the discovery of a remedy for cancer if it were parasitic than if it were non parasitic.

Mr FREDERIC S. EVE said that the changes antecedent to carcinoma could be best studied in superficial structures, skin and mucous membrane. It might be inferred that similar changes occurred in deeper parts although these could not usually be seen. He alluded to a few of these changes with a view to inquiring how they acted as determining causes of cancer. He mentioned epithelioma from mechanical causes, such as clay pipes, jagged teeth, soot, &c., from chemical causes, such as tar and petroleum; *and from* inflammatory and septic causes—namely, inflammations of mucous membranes such as leucoma and ichthyosis, old septic ulcers, chronic gastric ulcers, gall stone, chronic mastitis of the breast and persistent balanitis, and, lastly, granulomata and other lesions due to tubercle and syphilis. Mr Eve showed several drawings of illustrative cases. *In all the cases shown* certain conditions favouring the ingrowth of epithelium, which constituted cancer, were found. First, as the result of the antecedent inflammatory process, there was a migration of leucocytes into the corium or mucosa and often into the epithelium itself. By this means the normal boundary between *the epithelium and connective tissue was broken* down and, further, the lymphocytes and connective tissue cells furnished a granulation tissue into which the epithelial cells could intrude themselves and flourish. The majority of the processes were associated with an ordinary pyogenic or specific organism the products of which, acting for long periods *as continuous and abiding irritants to the epithelial* cells, stimulated them to active proliferation, altered their potentialities, and ultimately under the favouring conditions the subjacent connective tissues led to their assuming what might best be described as parasitic habits. These facts had a practical bearing—the curing, by operation if necessary, *of all those chronic, septic, or specific* lesions which might constitute pre-cancerous conditions. There were many examples of carcinoma not connected with "irritation," some of which might be explained by Cohnheim's theory. The cell was the carrier of malignant disease and in its change of nature must be sought the source of cancer. *Hope for the future rested with serum therapy. When a* serum or cytotoxin had been produced which would kill spermatozoa and arrest the movement of ciliated epithelium the discovery of a substance which would destroy cancer cells would not be far off. This had been already accomplished by Jansen in the carcinomata of mice which he (Mr Eve) had been *informed* by Dr Bulloch, *had* been transmitted by inoculation from mouse to mouse.

Dr J GEORGE ADAMI (McGill University, Montreal) contributed to the discussion a paper upon the Parasitology of Malignant Growths. He contended that no other view was possible at the present time than that the typical deciduoma was a syncytioma or chorio-epithelioma *malignum*. After considering the question in detail Dr Adami arrived at the following conclusions from a study of the syncytioma malignum. 1. There existed one form of tumour of highly malignant type in which the infiltrating cells were not those of the organism itself but were derived from another organism. 2. The infiltrative and invasive properties were not a new acquirement but were an exaltation of properties normally possessed by them. Under normal conditions there was an interaction of the invasive properties of those cells and the protective properties of the surrounding maternal tissues, by which interaction the extent of the invasion of the cells was strictly limited to the placental site. 3. The development of the syncytioma malignum had, therefore, to be attributed to either an increase in the invasive properties of the syncytial cells or a lessened resistance on the part of the maternal tissues, or a combination of the two. 4. If micro-parasites played any part in the production of the tumour, that must be either by exalting the infiltrative powers of the one or by lowering the resistant powers of the other. 5. Positive proof of the existence of such specific micro-parasites was still wanting and in its absence it was difficult to conceive how specific micro-parasites could bring about those results. 6. Admitting that micro parasites and their products were capable of inducing cell proliferation they had also to admit that other external agencies had the same capacity, so that micro-parasites at most might be one of the causes of aberrant cell growth. 7. The prevalent conception of cancer parasites as existing within the cancer cells involved the idea of malignant growths being the products of parasites acting within parasites. As shown by the study of the syncytioma the tumour cells themselves were essentially parasitic in the organism. He was willing to see in the long-continued action of micro parasites a process which might, like other modes of stimulation, initiate aberrant and neoplastic cell growth, but beyond that point they *seemed to be asked to* contemplate a most extraordinary state of affairs.

Dr J F PAYNE communicated a paper which dealt only with carcinoma. Many years ago there had been a debate at the Pathological Society of London as to whether cancer was to be regarded as a local or as a constitutional disease. It *was now known that a disease might be both constitutional* and local and this truth had been established by the study of specific diseases. The question thus raised was not without importance because it drew attention to the truth that cancer, besides being on its anatomical side a growth, had also another side by which it was comparable to specific *infective diseases. Recently cancer as a disease had been more* studied and pathologists had seen clearly and dwelt forcibly upon the analogies between cancer and infective disease, such as tubercle, syphilis, leprosy, and actinomycosis. If cancer were to be regarded as a specific disease the most convincing argument would be the discovery of its microbe and *the proof by experiment that it could produce the* phenomenon. But while this proof was still wanting there might be evidence which would justify a certain presumption that cancer was a specific disease. Such evidence, if forthcoming, would fall under three heads: (1) evidence of an initial lesion, of secondary lesions arising from this, *and of general intoxication*, (2) *evidence of communication* of the disease from one human being or animal to another, whether of the same species or not, by contagion, inoculation, or any experimental method, and (3) evidence of a specific local or geographical distribution, such as had been demonstrated, for instance, in malaria. It had been abundantly *demonstrated that cancer commenced as a local* process, it had not, however, been sufficiently considered that in a large proportion of cases the primary seat of cancer had many of the characters of the initial lesion of a specific disease, the chief difference was that the primary focus of disease in cancer was a growth *and the primary focus* in tubercle and the like was what was called inflammation. The process of forming secondary foci was also different, in tubercle a conveyance of the bacillus from one part to another was sufficient, while in cancer there was a conveyance or metastasis of cells. It must, however, be asked what it *was that* the transported cells carried with them which enabled them to go on growing and proliferating in the same manner as the primary growth. Was it a changed mode of growth impressed upon the cells of the primary cancer by an unknown cause and transmitted from them to their successors? or was it some small portion of a biological ferment or other substance capable of affecting the mode of growth? or was it a parasitic organism which required to be inclosed within a cell for transmission from one part to another? However these questions might be answered the fact remained that cancer had a primary seat and secondary seats set up by the conveyance of something from the primary seat. There was also general intoxication. The cancerous cachexia was clearly secondary to the absorption of something from the cancer itself. Cancer was not as a rule, a contagious disease, it did not spread from an affected person to those around and the exceptions to this rule were few in number. The situations of primary cancer were partly external and partly internal. Invasion of the skin was often preceded by so-called chronic irritation, traceable in cancer of the scrotum in chimney sweeps, in the cancer of petroleum workers, and in cancer of the lips believed to be produced by smoking clay pipes. Another possible path of invasion was by the internal surface of the body, especially by the alimentary tract, and if there were such a means of infection it might take place through some kind of food. Infection through the respiratory channels, which in many infective diseases formed an important medium, in cancer was of almost no importance. There remained a large class of internal cancers of which the possible connexion with external infection could not be traced—those of internal glands such as the kidney and especially of the reproductive organs in both sexes, including the mammary gland. Broadly speaking, 16 per cent., or less than one-sixth, of all cancers began on the external surface of the body, while 56 per cent. of the total mortality from cancer was due to carcinoma of the digestive organs. In males only 70 per cent., or in some countries 90 per cent., of the cases were those of cancer of the digestive organs. Primary cancer of the digestive organs was nearly always a surface lesion; it rarely began in the parenchyma of any solid organ. If there were any invasion of the body by the unknown cause of cancer all those primary cancers of the internal surface might be regarded, like external cancers, as initial lesions of the specific disease. Assuming that there was no clear evidence of cancer being a communicable disease, it might yet have a specific character if it were shown to be endemic. There was a good deal of evidence to show the local specific prevalence of cancer. It was a familiar fact that cancer was commoner in some countries than in others and in some parts of certain countries than in other parts. On the whole it must be concluded that neither climate, nor soil, nor density of population, nor occupation accounted for differences in the prevalence of cancer—in fact, the distribution of cancer, like that of malaria, seemed to be governed by specific, and not merely by general, physical conditions, though physical conditions might favour the prevalence of cancer as they favoured that of malaria. Another point strongly confirming the view that the distribution of cancer was specific was that in areas of high prevalence this prevalence was not uniform but was made up of a number of smaller areas with unequal rates.

Dr. H. MANDERS described the good results which he had observed in a patient who was considered to be suffering from abdominal cancer after treatment by high frequency currents.

Dr. J. R. LEESON having spoken the PRESIDENT closed the debate with a short speech. He remarked that there was no doubt that professional and public interest was thoroughly excited concerning the subject of cancer. Societies and commissions were being formed in most countries to inquire and to experiment. There was a commission in Germany, of which they had recently heard, and there was the Joint Committee formed by the Royal Colleges of Physicians of London and Surgeons of England, both of which had the subject under consideration. He looked forward to the day when they could treat cancer with as good a hope of success, perhaps by a serum, as they now could treat a case of diphtheria.

After the usual votes of thanks the meeting closed.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Sheffield on March 21st, Dr. S. Buckley, the President, being in the chair.—Dr. J. W. Martin (Sheffield) showed the following: 1. A specimen of a True Fibroma of the Left Ovary removed by abdominal section from a married woman, aged 34 years, the mother of three children, the last of whom was born seven months before the operation. The symptoms had been pain in the left ovarian region, dysmenorrhœa, and occasional dysuria. There was no ascites and the right ovary was healthy and was not therefore removed. The tumour was hard and nodulated and microscopical sections showed nothing but pure fibrous tissue. 2. A large Cystic Fibro-myoma of the Uterus from a patient, aged 24 years, a nullipara. The growth was of the size of a full-term pregnancy and being partly cystic caused much difficulty in diagnosis. The periods had always been scanty and for the previous few months they had been almost absent. The uterine cavity was not enlarged and an ovarian tumour was suspected. On opening the abdomen numerous adhesions required to be separated and the growth was then found to spring directly from the whole breadth of the fundus uteri. The tumour was amputated by flaps before and behind, the vessels were tied, and the stump was sutured. The uterus proper and the ovaries and tubes were left behind. The patient made a good recovery. The structure was that of a fibro-myoma. The occurrence of a growth of this nature at such an age was rare.—The specimens were discussed by Dr. Lloyd Roberts, Dr. Nathan Raw (Liverpool), the President, and Dr. W. Walter (Manchester), and Dr. Martin replied.—Dr. E. O. Croft (Leeds) showed a Uterus of about the size of a cocoanut which he had removed by supra-vaginal hysterectomy from a single woman, aged 39 years, by reason of a gradually increasing menorrhagia and the consequent anæmia. The outline of the uterus was fairly symmetrical but its cavity was found on examination to be very irregular. The specimen showed the unusual condition of a large number of fibromyomata of sizes varying from that of a hen's egg downwards, and all of them being practically of the submucous variety. One growth was becoming polypoid but the os uteri was closed below it. The patient made a good recovery.—Dr. Walter remarked that it would have been impossible to have removed completely the growths apart from the uterus even by incision of the uterine wall and that the operation performed undoubtedly gave the patient the best chance of recovery.—Dr. Croft also showed a large Fibro-myoma blocking the pelvis. The whole mass equalled the size of an eight months' pregnant uterus. The abdominal portion consisted of a spherical subserous growth about nine inches in diameter arising from the upper and anterior uterine wall. The pelvic portion grew from the posterior uterine wall downwards into the pelvis, which it practically filled. The uterine cavity lay more or less horizontally at the level of the pelvic brim and was not much enlarged. The general mass presented a circular groove corresponding to the brim of the pelvis and a depression posteriorly corresponding to the sacral promontory. As the lower growth was subserous it was found possible to raise it from the pelvis and the whole mass was amputated just above the cervix. The stump was sutured and the peritoneum was sutured across the pelvis. The patient had completely recovered. Pressure symptoms had been only slight, but owing to the conditions present a very slight increase in the size of the growth from any cause would have resulted in immediate and serious impaction.—Remarks were made by Dr. Walter and Dr. Lloyd Roberts, and Dr. Croft replied.—Dr. Walter showed the following: 1. A Uterus removed from a patient, aged 59 years. The menopause was passed 14 years previously and during the last two years there had been severe hæmorrhages. The cervix was short and patulous, but the uterus was considerably enlarged and a fungating mass could be felt growing from the fundus and body. The uterus was removed by vaginal hysterectomy. Histological examination proved the growth to be an adeno-carcinoma and a microscopical section was shown. 2. Sections of a Polypus removed from the cervix of a multipara, aged 37 years. The microscopical appearance was that of a round- and spindle-celled sarcoma. He therefore advised the patient to submit to hysterectomy, which was done a few days later. When the uterus was examined a small nodulated mass was found to be involving the mucosa and muscular wall just above the inner os. It had a slightly uneven surface and was of a greyish-pink colour. The microscopical appearance of the nodule was similar to that of the polypus.—Dr. Nathan Raw read a paper on Cæsarean Section Twice and Embryotomy Once in the Same Patient, with remarks on the question of sterilisation under such circumstances.—A discussion followed in which Dr. Lloyd Roberts, Dr. Walter, Dr. Martin, Dr. J. H. Keeling, and the President took part, and Dr. Nathan Raw replied.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held on March 19th, Dr. J. G. Douglas Kerr, the President, being in the chair.—Dr. Hamilton Cumming, in opening a discussion on Chronic Affections of the Kidney and Morbid Conditions of the Urine arising therefrom in Relation to Balneological, Climatic, and Dietetic Treatment, said that one was apt to connect the word climate in relation to kidney disease with the warmer climates. This was in the main correct, for though in the early stages of tuberculous or suppurative disease a bracing climate might be desirable, yet as soon as the kidney failed in excretory function the conservative influence of the milder climates became imperative. Whilst Nauheim baths were generally contra-indicated, hot baths, hot packs, and Turkish baths were distinctly useful, both by increasing the excretory action of the skin and increasing the peripheral circulation. As the condition of the pulse was the index of the arterial system, so it should be the guide as to diet; meat and fluid should be diminished where there was increased tension, whilst meat and a more stimulating diet were necessary where the pulse was soft and the heart was failing. The pulse should govern the exhibition of alcohol also. Taking Egypt as the ideal climate, how near and where could they approach it in (1) high mean temperature, (2) low relative humidity, and (3) small daily range? Speaking of Torquay Dr. Cumming said that its climate was decidedly beneficial to most cases of renal disease which was far from common amongst residents. It was his experience that renal cases did better about the sea level than on the hills, and there exercise was possible without undue strain on the crippled circulation.—Dr. G. Oliver (Harrogate) said that he (and he believed the profession generally) regarded high altitudes as unsuitable in granular kidney and more particularly when drifting towards the cardiac termination or when inducing dyspnœa; but on the other hand he believed that altitude was beneficial in cyclical albuminuria. The keynote of climate in chronic renal disease was equable warmth in winter and spring, in this country best illustrated by the south-west coast resorts, such as Torquay and Sidmouth, and abroad by Egypt and by Jamaica which was most promising. The study of blood-pressure was a useful guide in dieting. He strongly advised systematic increase of skin-elimination by heat (Turkish and Russian baths) and by D'Arsonval electrisation.—Dr. Leon Blanc (Aix les Bains) agreed with Dr. Oliver that douche-massage of Aix was good in kidney troubles, principally in gouty patients. It regulated the action of the circulation, diminished the arterial pressure, and put the skin into a better condition. He never gave strong sulphur or alkaline water. Water must be given hot. He considered that the effects of cold and hot water were different. Hot drinks remained in the tissues and dissolved the salts; cold drinks facilitated delimination. Iced or cold water produced congestion in the kidney. Hot or very warm climate must *be avoided. An equable and moderately warm climate* was desirable. Patients with kidney troubles must not be sent to Aix in July or August, when the climate was too hot.—Mr. A. G. S. Mahomed (Bournemouth) thought that full advantage should be taken of the relief action of the skin. This was more perfect than was always supposed. He had himself recovered urea from the sweat of renal patients. To get the full action of the skin in elimination he considered that the hygroscopic action of warm dry air was needed. For this reason he would choose the climate of Egypt. Unfortunately, home resorts that were warm were also moist as a rule. The dryest and warmest station should be selected.—Dr. McClure emphasised the important rôle which heightened blood-pressure played in the conditions under discussion.—Dr. E. Kingscote said that he considered albuminuria and tube casts to be no certain sign of renal disease.—Dr. G. A. Leon (Sidmouth) said that, in his opinion, the treatment of chronic Bright's disease should aim at eliminating the poison which was the cause of the high arterial tension rather than at merely reducing the rigidity of the vessels. This could best be effected by a mild climate, equable and not too dry; by baths, and in his experience no bath was better than a bi-weekly Russian bath; by diet, especially by abstinence from nitrogenous foods and all alcohol; and by free occasional purging.—Dr. F. Mouillot (Harrogate) said that amongst the most anxious cases in spa treatment were those which, in addition to symptoms requiring treatment, were found to have albuminuria. He, however, drew a marked distinction between cases in which the specific gravity of the urine was high and those in which it was low. The latter were unsuitable for powerful waters or large quantities, whilst the former were often greatly benefited by such treatment.—Dr. J. Groves (Carisbrooke) made some remarks and recommended the climate of Jamaica for renal cases.—The discussion was adjourned to April 16th.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on March 21st, Dr. H. Ashby (Manchester) being in the chair.—Dr. A. E. Sansom showed a case of Hodgkin's Disease in a girl, eight years of age. The glands on the left side of the neck were greatly enlarged and the spleen occupied the left half of the abdomen. The child was anæmic and the leucocytes were deficient. The disease started four years previously subsequently to measles.—Dr. R. Hutchison remarked upon the tuberculous nature of several examples of the disease which he had examined and upon the impossibility of determing post mortem from the naked eye whether they were tuberculous or not.—Dr. A. Morison and Dr. W. H. Kelson commented upon the case and Dr. Sansom replied.—Dr. F. Harcourt Gervis showed a case of Double Aortic Disease in a boy, aged 13 years, in whom a presystolic murmur was present at the apex.—Dr. Sansom thought that the presystolic murmur did not indicate mitral stenosis but was an example of Flint's murmur.—Dr. Morison was of opinion that pericardial adhesions were partly responsible for the enlargement of the heart and spoke of the propriety of surgical interference in selected cases.—Dr. Theodore Fisher (Bristol) considered that pericardial adhesions to the chest wall did not produce cardiac enlargement and consequently thought that surgical interference would be inadvisable even if the case could be diagnosed.—Dr. Harcourt Gervis replied.—Mr. Arnold Lawson and Dr. G. A. Sutherland showed a case of Congenital Proptosis in a child three years of age and thought that it was due to imperfect development of the base of the skull and the orbital plates.—Mr. W. H. H. Jessop discussed the case and agreed with the diagnosis.—Dr. Hutchison said that he had a similar case under his care.—Dr. E. Cautley referred to the high palatine arch in the case.—Dr. Sutherland in reply thought that whatever mental defects were present were only apparent and were due to defective hearing consequent upon the presence of post-nasal adenoids.—Dr. H. Campbell Pope showed a case of Infantile Scurvy in a female infant, aged eight and a half months, who had been fed on patent foods and had developed hæmaturia, periosteal hæmorrhages, and gingivitis. The symptoms had started three months before. The existence of hæmaturia had suggested the presence of renal calculus and the child had been examined by the x rays.—Dr. George Carpenter read a paper on a case of Scurvy in a Rickety Boy, aged five and a half years. The gums were affected and the child's dietary, owing to his *curious tastes, was very defective. Dr. Carpenter discussed* the etiology of scurvy and called attention to the difficulty which was experienced in arriving at a definite conclusion as to the exact causation of these cases.—Dr. Sutherland said that in his experience the prognosis was often grave.—Dr. Cautley discussed the question from the point of view of infant feeding and thoroughly endorsed the remarks made by Dr. Sutherland on the injurious effects of patent foods.—Dr. C. W. Chapman called attention to the value of fresh milk.—Dr. Ashby spoke as to the obscurity surrounding the causes of infantile scurvy.—Dr. Fisher thought that in fatal cases death might be due to secondary infection.—Dr. Carpenter replied.—Mr. W. P. Montgomery (Manchester) showed a specimen of an Inverted Meckel's Diverticulum which had formed the apex of an ileo-colic intussusception. The condition was, he stated, a rare one, there not being more than six cases on record.—Dr. Fisher showed a specimen of Congenital Disease of the Heart from a child, aged four months, in which a wide communication was present between the aorta and pulmonary artery, and attached to both pulmonary and aortic valves were large vegetations. Dr. Fisher also showed a Stomach from a case of Diphtheria in a child, aged three years, which was dotted over with numerous petechiæ; there were no petechiæ elsewhere, the large intestine excepted. There had been hæmatemesis two days before death.—Dr. Ashby read a paper upon a case of Combined Empyema and Purulent Peritonitis. A girl, aged eight and a half years, was seized with vomiting and diarrhœa followed by pleuro-pneumonia and peritonitis. An empyema and suppurative peritonitis followed. Pneumococci and the micrococcus tetragenus were found in the pus of the empyema and the micrococcus tetragenus in the peritoneal pus. The girl made a good recovery.—Dr. Sansom complimented Dr. Ashby on his paper.—Dr. Fisher said that he had made post-mortem examinations of cases of combined pleural and peritoneal infections due to the pneumococcus and other organisms.—Dr. David Nabarro called attention to the pathological records of the Evelina Hospital for the past year of cases in which peritonitis was associated with empyema.—After remarks by Dr. H. J. Simson and Dr. E. W. Goodall Dr. Ashby replied.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—The sixth meeting of the session of this society was held on March 25th, Mr. W. B. Holderness, the President, being in the chair.—The President exhibited two cases of Functional Disturbance of the Heart.—The adjourned discussion on Dr. E. S. Norris's paper on 1000 Cases of Vaccination and

Revaccination was resumed by Dr. W. A. Ellison who said that it was necessary for the medical profession to prove to the public that vaccination if properly performed was never productive of harm. When bad results were attributed to vaccination a careful examination of all the evidence was necessary and it would appear that frequently, as in a case instanced by him, the *modus operandi* was at fault. Dr. Ellison inquired whether members were agreed upon the best method of vaccinating. He wished also to have the opinion of others as to the employment of shields and other artificial means of protecting the sore.—Dr. Norris, in reply, briefly re-stated the conclusions that he had arrived at, the main points being (1) the high protective influence of revaccination which afforded an even higher protection than small-pox itself; and (2) the fact that primary vaccination did not protect against the malignant form of small-pox.—Dr. F. H. Hawkins (Reading) read a paper entitled "The Treatment of Acute Lobar Pneumonia." After a few remarks upon the nature of the disease the various points to be attended to in treatment were discussed in detail. Rest in the recumbent position was first insisted on and stress was laid on the importance of keeping up the patient's strength by feeding. Care should be taken to avoid distending the stomach by too much food, as by such means the heart's action might become seriously embarrassed. Free drinking of cold water was advised both for its action as a depurating agent and as a stimulant. Attention to the alimentary system was considered, a few grains of calomel in the early stage of the disease being useful. Vomiting should be met by a mustard poultice to the epigastrium and flatulence often yielded to bicarbonate of soda, hydrocyanic acid, and calumba. The strength of the patient could also be kept up by the administration of diffusible stimulants of the ammonia group. With regard to local treatment, the use of linseed poultices was highly recommended and in cases where the temperature was high the local application of ice was advised. For the acute pain when caused by engorgement of the lungs the local application of ice was indicated but when pleurisy and engorgement occurred together a few leeches would give quick relief. In this connexion the use of morphia was alluded to, great caution in its administration being advised. The use of strychnine as a respiratory stimulant was highly spoken of, particularly when a large area of lung was involved. In these cases the administration of oxygen was also recommended. The temperature should not be specifically treated, but when associated with other grave signs it could be best met by the use of the ice cradle or of ice-packing. Dr. Hawkins expressed his opinion that consolidation of the lung did not always produce dilatation of the right heart, and cases were cited in support of this statement. He thought that many cases of failure of the heart were due to fibroid degeneration, the cause being the toxin acting upon that organ. Here the use of strychnine was warmly commended, its use being specially indicated at or about the crisis. Digitalis, too, in certain cases was useful. The question of sleep was next discussed at length, Dr. Hawkins's experience being that in many cases a deep sleep was bad and that it was well to rouse partially the patient occasionally to administer food. When sleeplessness was persistent bromide of potassium was indicated. Restlessness was best met by the wet pack and chloral hydrate in from 15- to 20-grain doses was highly spoken of. He seldom or never used opium. For delirium bromide of potassium was useful, as was camphor for low muttering delirium. When delirium was due to exhaustion alcohol was indicated. Lastly, the use of alcohol in pneumonia was discussed at length and the paper concluded with a *résumé* of the indications for administering or withholding this drug.—Dr Norris, Mr. Arnold Thomson, Dr. O. R. Elgood, Mr. W. H. Beresford, Dr. G. E. Hale, and the President having offered remarks Dr. Hawkins replied briefly.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—A meeting of the Section of Obstetrics was held on March 14th, Dr. Andrew J. Horne being in the chair.—The Secretary exhibited for Dr. J. H. R. Glenn a Uterus removed by Retro-peritoneal Hysterectomy, showing peculiar venous attachments.—Dr. Alfred J. Smith exhibited Three Fibromatous Uteri showing mucoid degeneration.—Dr. R D. Purefoy exhibited a Fibroid Uterus and a specimen of Ruptured Tubal Pregnancy.—Dr. Horne exhibited a specimen of a large Uterine Polypus.—Dr. Purefoy read his report of the Rotunda Hospital, Dublin, for the year 1900-1901. During the year 1905 women were admitted to the maternity department of the Rotunda Hospital, of whom 1610 were confined and the others were discharged not being in labour. Among those treated were found some of the rarest concomitants of pregnancy—viz., emphysema, puerperal aphasia, and pulmonary embolism. During the year three deaths occurred: (1) that of a patient who was moribund on admission; (2) that of an emaciated cachectic patient who was some days in labour before admission and who succumbed after Cæsarean section which was rendered necessary by uterine fibroids; and (3) that of an elderly patient with contracted pelvis in whom death occurred after induction of premature labour, this being unusually protracted by inertia of the uterus and morbid adhesion of the placenta. The dispensary attendances during the year were 10,741. In the extern maternity department 2175 cases were treated, including 286 cases of abortion, 18 cases of accidental hæmorrhage, six cases of placenta prævia, 27 cases of post-partum hæmorrhage, and seven cases of prolapse of the funis. In the intern maternity department 1616 patents were treated, of whom 549 were primiparæ. The operations performed included 66 forceps cases, 24 cases of manual removal of the placenta, 10 cases of version, and one case of Cæsarean section. There were 19 cases of accidental hæmorrhage, nine cases of placenta prævia, 36 cases of post-partum hæmorrhage, and one case of secondary hæmorrhage. The presentations included 43 cases of breech, five of face, eight of footling, 20 of occipito-posterior, six of transverse, and 10 cases of prolapse of the funis. Of multiple pregnancy there were 14 cases, all of which were twins. Episiotomy was practised in 18 cases, chiefly as an aid to forceps extraction—the single incision in the mesial line was invariably adopted. Ophthalmia occurred in four cases during the year. In all instances the attack was mild and had entirely subsided before the infant left the hospital. A red vaginal discharge, having the characters of menstrual fluid, was observed in two infants, beginning on the second day after birth and lasting for four or five days. The causes of morbidity included mastitis in four cases, influenza in two cases, bronchitis in three cases, phthisis in one case, pleurisy in one case, mania in one case, syphilis in two cases, erythema in two cases, inflamed piles in one case, and rheumatism in one case. In 12 cases the cause of morbidity was not ascertained. The report dealt very fully with the case of that rare and interesting condition, puerperal aphasia, of which Dr. Purefoy's case was an example. The patient, aged 23 years, was a primipara of healthy appearance. Her pregnancy had proceeded most favourably till the beginning of the ninth month, at which time her husband, one day returning from work, found her in bed and unable to speak anything but the word "Yes." At the same time he observed large quantities of vomited material on the floor. The case of pulmonary embolism occurred in a primipara, aged 34 years, who made a good recovery. Johnson and Sinclair had recorded seven cases of this affection, but this was its first occurrence during Dr. Purefoy's term of mastership.—At the termination of the reading of the report it was decided to postpone the discussion until the next meeting of the Obstetrical Section and the meeting terminated.

MANCHESTER MEDICAL SOCIETY.—A clinical meeting of this society was held on March 19th, Dr. Thomas Harris, the President, being in the chair.—Mr. Joseph Collier showed the following surgical cases: (1) a man on whom Excision of the Left Knee-joint had been performed for Rheumatoid Arthritis; (2) a boy after Excision of the Upper Half of the Fibula for Central Sarcoma; (3) a woman in whom the Dilated Vermiform Appendix had been adherent to, and communicated with, the Bladder, so that fæces passed per urethram; laparotomy had been performed and the appendix removed, the patient making a complete recovery; and (4) a girl on whom Erasion of the Knee-joint had been performed; the patella had been kept freely moveable and the extensors had consequently retained full control over the joint.—Dr. Joshua J. Cox showed a boy, aged seven years, and his sister, aged nine years, who were both suffering from Infantile Myxœdema and were recovering rapidly under thyroid treatment. When the children came under observation at the Clinical Hospital, Manchester, five months ago they were exceedingly dwarfed, lacked intelligence, could not dress themselves, did not play like other children, and had the facial and other signs of infantile myxœdema. Their parents were healthy and well-grown and had five other children, all of whom were normal; no tuberculous or neurotic family history could be obtained. The mother stated that all her pregnancies and labours had been natural and that she had no fright while carrying the two children now suffering from infantile myxœdema who were intelligent and of average height and weight until four years of age, after which period they developed neither mentally nor physically. Each child was now six inches shorter and 14 pounds lighter than the normal child at a corresponding age. The progress made under thyroid treatment was remarkable. The children were growing, were increasing in weight, were rapidly becoming more intelligent, and could dress themselves. That week they had been admitted to the School for Defective Children recently established by the Manchester School Board. Dr. Cox remarked that it was unusual to find sporadic cretinism in males and still more uncommon to find two cases occurring in one family.—Dr J. Gray Clegg showed a series of Ophthalmic Cases, including optic neuritis, optic atrophy, thrombosis of the central artery of the retina, tuberculous kerato-iritis, and central choroidal opacity of the lens. —Mr. J. Howson Ray showed the following cases: (1) a man who had previously been submitted to Laparotomy for Gangrenous Appendicitis with general septic peritonitis; the appendix, which was removed, was shown; it contained two concretions; (2) a girl with Excision of the Elbow for Tuberculous Arthritis, where the disease had already divided each of the three bones completely at the usual saw-line, so that the operation needed only scalpel, forceps, and spoon; (3) a case of Recurrent Molluscum Fibrosum of the Face, Scalp, and Orbit, with arterial angeioma in the diploë and lymphatic obstruction; and (4) a child, aged seven months, successfully treated six weeks previously by laparotomy for acute ileo-cæcal intussusception of four days' duration — Mr. C. Roberts showed the following surgical cases: (1) a case of Traumatic Aneurysm of the Dorsalis Pedis Artery, the treatment proposed being to excise the sac; (2) a case of Psoas Abscess pointing in the groin and simulating a femoral hernia; (3) a case of Tumour of the Abdominal Wall, probably of a malignant nature, arising beneath the scar of an operation for the radical cure of a left scrotal hernia; and (4) a case of Epithelioma of the Tongue, illustrating the difficulty of early diagnosis from syphilitic disease of that organ and the misleading initial improvement after administration of potassium iodide.

Forfarshire Medical Association.—A meeting of this society was held on March 6th, Professor D MacEwan, the President, being in the chair —Professor J. A C Kynoch showed (1) a specimen of Fibroma Uteri removed by pan hysterectomy for repeated hæmorrhages and retention of urine, and (2) a Fibroid Polypus of the Uterus removed post mortem in which there had been no hæmorrhage.—Dr. R. C Buist read a paper on Albuminuria in Pregnancy. The paper emphasised the value of routine examination of the urine for albumin in all pregnant women and of a milk diet when albuminuria in pregnancy had been discovered. Personal experience of routine examination showed about 2 per cent. of his confinement cases with albuminuria. When the examination showed albumin it was usually possible to avoid eclampsia by giving the patient milk only. Six pints a day was the amount that should be aimed at and suggestions were made for cases where simple milk was not well taken. Notes were given of cases to illustrate various points. Professor Kynoch, Dr J Mackie Whyte, Dr G. Halley, and Dr. A. J. Duncan spoke on the paper, and Dr. Buist replied.—Professor C R. Marshall read a paper on the action of a new purgative termed "purgatin" This, he explained, was the first synthetic purgative built up on the type of the active principles of aloes, cascara sagrada, rhubarb, and senna which had been put upon the market. It was the outcome of the researches of Tchirch who had shown that the "eccoproticophor" group in the drugs was probably anthraquinone or methyl-anthraquinone. Vieth, experimenting on cats, had found that of anthraquinone derivatives, anthrapurpurin and flavo-purpurin were the most suitable purgatives, but as they were somewhat uncertain in action and tended to induce colic he had sought for, and had found, what had now been put on the market under the name "purgatin" This substance had been investigated therapeutically by Ewald, Stadelmann, and Ebstein who agreed in the main in ascribing to it a gentle but certain action in appropriate doses It was best employed in simple or "functional" constipation, and the dose recommended was from seven and a half to 15 grains, but 30 grains were often required. The main objection to its use was the reddish colouration of the urine which it induced Professor Marshall gave an account of his own observations made on himself and said that he agreed in the main with the above-mentioned clinicians. He thought that it would be of use as a simple purgative but stated that the large dose necessary in most cases and the absorption which occurred were distinct objections. Upon the latter he dilated at some length, and also mentioned that in large doses distinct renal irritation was induced—a symptom not hitherto described.—Some questions were asked regarding reactionary constipation and weakness after its use, to which Professor Marshall replied.

Nottingham Medico-Chirurgical Society.—A meeting of this society was held on March 19th, Mr. E. C. Kingdon, the President, being in the chair.—Dr. C. Bell Taylor showed two cases of Recent Cataract Extraction.—Mr. W. M Willis showed the following cases: 1. A boy after Arthrectomy for Tuberculous Disease of the Knee-joint. The patella had been sawn across and all the synovial membranes and semilunar cartilages had been removed. No drain was used. The patella was wired and the skin was sewn up. The wound healed well, leaving the boy with a sound limb, and his general condition had greatly improved since the operation. 2. A woman after operation for Perforated Gastric Ulcer. There was a history of sickness of two years' duration but there had never been hæmatemesis. 3. A case of Congenital Dislocation of both Hip-joints. (A skiagram was shown)—Dr. Bell Taylor read a paper on the Art of Extracting for Cataract and exhibited a patient on whose right eye he had operated for cataract in his eighty-sixth year and on whose left eye he had operated for cataract in his ninety-sixth year. The pupils were central, round, and moveable. The patient could read for hours. Another patient, aged 60 years, who was operated upon for cataract in both eyes four years ago was also introduced upon recovery from the operation. He had been employed in the furnace department of one of the principal railways. The glare and heat to which he was exposed in striking red-hot metal for hours daily without glasses were necessarily very trying Both eyes were, however, perfect; the pupils were central and moveable and the sight was excellent, while there was not the slightest trace of operative interference. Dr Bell Taylor contended that the secret of success lay in the use of a very narrow knife and in the formation of a very wide wound and that, after extraction, a perfect and moveable pupil (as in aphakial animals) largely compensated for the absence of the lens —The paper was discussed by the President, Dr. F. R Mutch, Dr. W. G. Laws, Mr. R. G. Hogarth, and Mr. F. J. Lander, and Dr. Bell Taylor replied.—Mr. W. E M. Wright read notes of a case of Malignant Stricture of the Œsophagus occurring in a man, aged 64 years, and showed a specimen of the larynx in which there was a large perforation posteriorly from malignant ulceration extending from the œsophagus.

Midland Medical Society.—The ninth meeting of the session of this society was held at the Birmingham Medical Institute on March 19th, Mr. A. Oakes, the President, being in the chair The following officers were nominated for election —President: Mr. Langley Browne. Treasurer Mr J Garner Secretaries: Mr Christopher Martin and Dr J D Stanley.—Mr Jameson Evans showed a woman, aged 59 years who had been under his care since the end of January, 1902. She was suffering from a typical diffuse Keratitis over the Lower Half of the Right Cornea. At one part it was infiltrated with fine vessels forming a distinct "salmon-patch." She was making satisfactory progress towards recovery under treatment with mercury potassium iodide, and atropin drops Her family history was interesting. She had had six children and two miscarriages. Two of the children had suffered from eye troubles; one of these, a girl, aged 22 years, was shown at the meeting. She showed corneal nebulæ the result of interstitial keratitis for which she had been under treatment at the Eye Hospital eight years ago. She had marked Hutchinson's teeth and was deaf —Dr. W. J. McCardie showed Mr. R. W. Lloyd's Paper Bag for Clover's Inhaler. The bag was described in The Lancet of Jan. 11th, 1902, p 99 —Mr. L. P. Gamgee showed a Kidney the pelvis of which was completely filled by a villous papilloma. The patient was a man, aged 50 years, who had suffered from

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

A Baillie Lecture

ON

THE SEED AND THE SOIL.

Delivered at St. George's Hospital on Feb. 3rd, 1902,

By W. HOWSHIP DICKINSON, M.D. Cantab.,
F.R.C.P. Lond.,

HONORARY FELLOW OF GONVILLE AND CAIUS COLLEGE, CAMBRIDGE;
CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE
HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

"Behold the sower went forth to sow; and as he sowed, some seeds fell by the way side, and the birds came and devoured them: and others fell upon the rocky places, where they had not much earth: and straightway they sprang up, because they had no deepness of earth: and when the sun was risen, they were scorched: and because they had no root, they withered away. And others fell upon the thorns, and the thorns grew up, and choked them: and others fell upon the good ground, and yielded fruit, some a hundredfold, some sixty, some thirty."—Matthew xiii. 3.

Gentlemen,—The pathology of the present day is above all things bacteriological. It inclines to attribute all diseases with which bacteria have been associated simply and singly to a bacterial origin, confidently assumes that where microbes have not yet been found they will be, and sanguinely trusts that when found they will submit to control with a tractability in the future which our experience of the past gives us no great warrant to expect. I read the other day in The Lancet of a bacillus of fatigue and should hear without astonishment of bacilli of political or theological bias impelling their bearers to toryism or radicalism, scepticism or credulity.

One of the greatest discoveries of the past century, I may even say of all time if greatness be measured by utility, is connected with the recognition of micro-organisms, their exclusion by cleanliness and destruction by antiseptics. But it must be allowed that antiseptic surgery is more successful than is antiseptic medicine; the two are on very different footings: one has to do chiefly with suppuration, in the first instance at least a question of reachable surface, the other has to do with disease which is out of reach before it comes to our knowledge and has entrenched itself in the deep organs or found a harbour in the blood itself. One is chiefly concerned with the streptococcus and staphylococcus, comparatively simple sources of mischief, the other with bacilli of various kinds and complicated relations with disease.

Encouraged as we must be by the results of antiseptic surgery, we must approach with wary steps the very dissimilar problems which medicine presents. To these my text chiefly applies. I would venture to beg my hearers not to be so eager to secure what is new that they lose what has been acquired in the past. In grasping the new pathology of microbes and bacilli let us not quite ignore the ascertained facts of old time with regard to heredity, tissue and diathesis. It is for the purpose of recalling some of the old truths, none the less true because they are out of fashion, that I address you to-day.

Bacilli may be the roots, or rather the seeds, of much, if not of all, evil. It seems to us that we should get on better without them. But let us not be too sure of that; some sorts have uses that we know of, others may have uses that we do not know of. They take their part in the scheme of creation, though to us it may be a mischievous one.

"From Nature's chain whatever link you strike,
Tenth, or ten thousandth, breaks the chain alike."

As to the bacilli of disease, we from the human point of view cannot but regard them with disapproval. Our soul's sincere desire must be to get rid of them. But, unfortunately, like other enemies, they are not very amenable to frontal attack. They are more readily influenced by indirect than direct methods, by means which without bearing immediately on the bacillus render its abode unattractive or untenable.

We may learn much from the vegetable kingdom. The distribution of plants, within the range of the seed, is regulated by the local conditions which the seed meets with—soil, moisture, temperature, light, and what not. Of course, there is no growth without the seed. *Omne vivum ex ovo* holds good now as in the time of Harvey. But the seed may be indiscriminately and widely spread; within certain wide boundaries it may often be said to be ubiquitous, so that the whole question of distribution turns not upon the seed but the soil, not upon the germ but its reception. Why do oaks and beeches grow in the fat levels of the New Forest, the ash and the thorn where the land is hilly and poor, and sycamores about the wind-swept homesteads of Cornwall? Not because the seed was, in the first instance, placed there more than elsewhere, but being placed there, as elsewhere, it found conditions to suit it. This is the whole story of the whereabouts of plants, the supreme law of the vegetable kingdom. The seed will fructify where it is satisfied with its entertainment and perish where it is not. For this reason, and not because the seed is conveyed there more than elsewhere, stonecrop, moss, and lichen gather on their appropriate roofs and rocks and the ivy on mouldering walls. Thus ferns multiply in their variety in one district and not in another. Ferns flourish with warmth and moisture and assure us by their presence of these qualities in the atmosphere. Maidenhair has its chosen localities in shady caves and crannies where the necessary conditions are combined, and may be so far from any other growths of the same sort that we can but wonder whence the seed was derived. Passing from natural beauty to what is repulsive we learn a similar lesson from the degraded nettle with its associations of squalor and filth. The seed may be everywhere in a country district but the weed will be found especially where human excrement has been deposited.

Examples of the paramount influence of soil or nidus in the determination of vegetable and animal life are never absent from our eyes. Take the domestic cheese. Why does one cheese breed green mould, another mites, and a third maggots? It may be that the three are kept in the same larder, exposed to the same external influences, and sown with the same seeds of animal and vegetable decay. Yet in the Stilton will gather green mould, in a fat cheese maggots, and in a lean one mites. The difference is in the cheeses themselves, not in what they have been sown with. The germs are common to all, those only will germinate which like their situation. So it is when the soil is the human body. Germs, be they vegetable or animal, are continually on the wing or in the swim, they swarm around us on every side; and if we knew how many and of what sorts are continually besprinkling us with the seeds of disease we should live in continued dread of being assassinated by these minute enemies. It is probable that no one who has lived in London has failed to give lodgement to the organism of typhoid fever, though he may have escaped its effects, and so with many other diseases. So it must be presumed to be with most of the infectious disorders which are common in ordinary life. Why is it, then, that we are not all infected with everything?

Relapsing fever may supply an illustration. This disease is occasioned by a special bacterium, the spirillum, which finds admission into the blood, presumably always by way of contagion. Yet it is intimately associated with starvation, insomuch that its accepted synonym is famine fever. The disorder is not directly caused by starvation but by the spirillum which is descended from its own kind. The want of food does not directly engender the microbe but fits the body for its entertainment. Given the suitable state of body, the appropriate germ will find it out though to our imagination completely out of reach. Our exemption rests not so much on the absence of the bacillus as on the absence of the conditions which it requires. Our forefathers did not fail to notice the connexion between depression and febrile disorders which is exemplified by remittent fever and possibly applies also in some degree to typhus fever. Says Addison, in the *Tatler*: "Physicians observe that the poorest and most dispirited blood is most subject to fevers."

Limiting the dissemination of the morbific germs by isolation is at best an imperfect measure. Our salvation largely depends on our insusceptibility, though, of course, we sometimes have to thank the feebleness or attenuation of the poison which reaches us. The human body can deal with a certain amount of the seeds of disease without becoming diseased. There is such a process as phagocytosis, in virtue of which the white corpuscles play the part of the birds and devour the seeds. There is such a condition as immunity even when the poison is active and concentrated, a state which may be either congenital or acquired, which is very real however imperfectly understood, by reason of which the morbid germs are inhibited from further proceedings. About immunity there is much that is mysterious, but at any rate we know, as did Mithridates, that exposure to small doses or attenuated conditions of a poison, whether it be that of a snake, or of small-pox, or what not, will produce insusceptibility to larger or stronger. It is probable that most of us are habitually acquiring invulnerability to our besetting enemies by exposure to their modified attacks. This, of course, is the principle of vaccination. But this is not the only, or even the chief, means by which the spread of disease is restricted. There are qualities proper to the individual which we do not understand but cannot fail to recognise, which make some resistant of disease to which others are prone. The seed is not wanting but the soil is barren to it. These powers of resistance may be congenital or acquired and may vary in the same individual at different periods of life. Some are resistant of small-pox, others of the great pox. Watson mentions an old woman who went from village to village nursing small-pox patients. She had never had small-pox and she believed herself to be proof against it. She ultimately caught it and she died from it, but not until she had reached the age of 84 years. At the Hospital for Sick Children in my time were two nurses, a mother and a daughter, neither of whom had had scarlet fever, while both were thought to be impervious to it. They were habitually employed in the scarlet fever ward and in attendance upon such cases in private. Every epidemic, be it of what sort it may, furnishes instances of invulnerability. Of the numbers exposed to the infection only some, probably a minority, are attacked, some diseases being more comprehensive in their grasp than others. Why do the majority escape? 12,000 soldiers were shut up in Ladysmith where typhoid fever was raging; 1472 contracted the disease, or about one in eight. What saved the seven? Was it that the poison was not fairly distributed or was it because all were not equally susceptible? It is probable that the infection was distributed with much impartiality but that all were not equally prone to take it. A remarkably localised epidemic of typhoid fever occurred at Caterham in the year 1879,[1] which was traced to a workman suffering from the disease whose evacuations were allowed to enter a well belonging to the waterworks which supplied the place. Caterham at the given date had 5800 inhabitants, of whom 81 contracted the disease. The poisoned water was supplied to 419 houses from which these 81 cases were derived—an average of one case to five houses. Why did so many houses escape and so many persons in the average house? There was no blood upon the lintels to warn off the destroying angel. The water, as we may presume, was supplied impartially to all, though we have no assurance that all alike drank of it. Yet we cannot imagine that in four out of every five houses no water was drunk and we must attribute the immunity of their inhabitants, at least partially, to something other than their having abstained from it—in other words, to their insusceptibility.

But it is not necessary to multiply instances of what must be familiar to all who have considered such questions. Many of us—I may even say most of us—are frequently exposed to infection without being infected in virtue of the unproductiveness of the soil on which the seed falls. Some persons are prone to succumb as others are to resist. There are conditions of the body, whether of blood or tissue, which make it apt to entertain or to reject certain infective diseases—in other words, to accommodate or to refuse to accommodate certain bacteria. Increased susceptibility is the determining factor in many diseases, at the head of which class we may confidently place the family of tuberculoses, while in it we may provisionally include the less numerous but more obtrusive group of the cancers. As we must have regard to the known before we venture upon the unknown any speculations as to cancer may properly be postponed until we have taken stock of the assured facts and strong probabilities which relate to the subject of tubercle.

It is obvious that to originate tubercle the seed in the shape of the bacillus is essential; but it remains to be asked why of a number of individuals who receive the seed equally some should encourage its growth and others not. In one person the bacillus falls on barren ground; in another it yields fruit a hundred-fold. The determining difference in ordinary life is in the individual, not in the germ or its distribution. We can imagine an isolated item of humanity on some mountain summit or isle of the ocean congratulating himself if on nothing else on his exemption from tubercle; but in common social conditions the seed is sown broadcast and the vital question is not where it will be deposited but where it will grow. As predisposing causes of tubercle, influences which fit the soil for the seed, heredity may be placed first. Next as a distinct and recognisable antecedent, at least of pulmonary tubercle, comes local inflammation. Then comes alcoholism. Next come circumstances which, in vague phrase, lower the vitality—want of food, frequent child-bearing, over-lactation, over-work, mental distress and anxiety. Next may be mentioned conditions which are not less surely provocative of tuberculosis because their mode of action is indefinite or complicated. Chief among these are overcrowding and defective ventilation. A cause of phthisis which is accepted generally but not universally is living on damp earth. Some of these causes of disease act obviously upon the soil, so to call the human body proper; by impairing nutrition they increase the fitness of the tissues to entertain the bacillus; while overcrowding and want of ventilation are attended also with an increase of the seed owing to over-production and deficient removal.

Some of these predisposing causes of tuberculosis or of phthisis may bear a word or two of amplification. The predisposing cause may be more important than the exciting cause; in urban communities the microbe is always with us, it needs the antecedent suitability to be effective.

1. *Heredity.*—Few facts in etiology are more surely ascertained than the hereditary nature of phthisis. In some families it cleaves like a curse to successive generations as it is said to have done to the House of Tudor. It is not unknown for all the members of one generation, or almost all, to be swept off by it, each individual becoming subject to it, not when exposed more than at other times to the attacks of the bacilli but on attaining the time of life most suitable to their development. The hereditary nature of this disease is so fully recognised that it has been thought necessary to provide an explanation in the transmission of the bacillus from parent to child. The microbe enters with conception, like congenital syphilis or original sin, and remains dormant for perhaps 20 or 30 years before it declares itself. It displays none of the indecent haste to attract attention which is manifested by congenital syphilis, but holds its hand and bides its time until its entertainer has reached a certain age. If this long suspension and ultimate recovery of its mischievous properties do not commend themselves to our sense of probability we must suppose that what is inherited is not the special organism of the disease but the suitability to accommodate it; that, in short, it is a question, not of the seed, but of the soil. A certain bodily aspect is a frequent though not a constant accompaniment of pulmonary phthisis—the fair hair, the delicate skin, and the composition of white and red.

2. *Local inflammation.*—Next among the distinguishable antecedents of tuberculosis in its pulmonary manifestation may be placed inflammation of the respiratory organs. Clinical evidence appears to leave no room for doubt that inflammatory conditions, especially of the nature of lobular pneumonia, are frequent antecedents of tuberculous disease, with the presumption—as yet I speak only clinically—that *foci* of inflammation are especially inviting to the bacilli of tubercle. The indication is that tuberculous often succeed upon inflammatory conditions which are at first only catarrhal or without special character. The vulgar notion of a cold which settled on the lungs and ended in a consumption has a profound truth at the bottom of it. When my chief employment was making post-mortem examinations I repeatedly had occasion to notice the association of tubercle with pulmonary inflammation in circumstances which appeared to show that the inflammation was primary, the tubercle secondary—as, for example, when the tubercle was concentrated on one lobe which had formerly been the seat of pneumonia. Speaking clinically, however, it would seem that the kind of inflammation most often followed by tuberculosis is lobular pneumonia or capillary bronchitis—a conclusion which is warranted by the time-honoured observation that measles and whooping-cough are both frequently followed by, and are apparently productive of, tuberculous disease. Professor Sims Woodhead reminds me that as a modern experience the same may be said of influenza. The frequent association of tubercle with the diseased states of lung produced by the inhalation of irritating particles, as in the case of needle-grinders and many whose trades

---

[1] Report of the Local Government Board by Dr. R. Thorne Thorne. 1879.

compel them to breathe dust of various kinds, is another instance of the development of tubercle secondarily to inflammation at first non-tuberculous

So far I had proceeded on clinical grounds and broad pathology, dealing with large results rather than minute modes of action, as becomes one who does not profess the technical skill of the bacteriologist. But I am fortunately enabled by the courtesy of Professor Sims Woodhead to supplement my own deficiency by his special knowledge; and it is no small satisfaction to me to find that we have both reached the same conclusion different as our roads have been.

> "As many arrows loosed several ways
> Come to one mark."

Professor Woodhead writes in a letter for which I have to thank him, "I think there is not the slightest doubt but that tubercular lesions are, as it were, superimposed on catarrhal pneumonias. Further, I believe that a perfectly healthy lung is seldom if ever primarily infected by the tubercle bacillus. The so-called primary tubercular catarrhal pneumonias commence as a rule in slight inflammatory affections which afterwards become infected with the *tubercle bacillus*" The conclusion indicated by large considerations is thus confirmed by minute research.

3. *Alcoholism.*—Next comes the question of alcoholism in relation to tuberculosis. What I hold to be a mischievous fallacy prevailed until recently, and perhaps is not even yet entirely defunct. 30 years ago,[2] in the course of some inquiries on the pathological effects of alcohol, I came upon evidence, which appeared to me conclusive and which has influenced later medical opinion, to the effect that this agent does not prohibit but encourages the growth of tubercle. With a view of ascertaining the effects of alcohol in the production of organic disease I applied myself to the admirable records of this hospital and by their means instituted a detailed comparison between the post-mortem appearances of persons whose occupations had to do with liquor—brewers' men, potmen, waiters, and the like—and others whose callings necessitated no familiarity with it. I relied upon the general rule, as applied to the class from whence the London hospitals draw their patients, that those who get drink for nothing will drink more than those who have to pay for it.

> "How oft the sight of means to do ill deeds
> Makes ill deeds done."

The comparison, it is needless to observe, was not between liquor and no liquor, one difficult to place on a sure and sufficient foundation, but between more and less, based on the fundamental character of the Anglo-Saxon The records to which I have referred presented in 30 years the post-mortem examinations of 149 traders in drink, to which I opposed the same number of post-mortem examinations of persons not so occupied. The results with regard to tubercle were striking Of the alcoholics 61 had tubercle of the lung and of the non-alcoholics 44 With *regard to other organs and structures liable to* tubercle—the brain, the liver, the kidneys, the spleen, the bowels, the mesenteric glands, and the peritoneum, every one of these in the alcoholic class displayed tubercle at least twice as often as in the non alcoholic. Nothing could be more consistent in associating tubercle with drink. But before arriving at a final conclusion it may be as well to ask, having regard to modern knowledge, whether the preponderance of tubercle among persons concerned with liquor can be attributed to their living more within doors or being more debarred from fresh air than persons not so concerned. No doubt waiters, cellarmen, publicans, barmen, and brewers commonly pursue their employment in houses; on the other hand potmen and draymen do so in the streets. The comparison between the two classes as between indoors and out of doors comes to this. Of the 149 persons dealing with liquor 84 were presumably occupied indoors and 65 out of doors. Of the same number of persons not dealing with liquor 45 were occupied indoors and 59 out of doors, while there remained 45 the place of whose employment was uncertain or variable It would seem that there is no such preponderance of fresh air or the want of it in either case as to account for the very decided preponderance of tubercle under drink. We *may* therefore conclude, and that confidently, that alcohol promotes tubercle and that not because it begets the bacilli but because it impairs the tissues and makes them ready to yield to the attacks of the parasites. "Good store of fertile sherris," though it cannot supply the seed, manures the soil.

4 *Exhaustion and depression*—No illustrations are needed in support of the common experience that pulmonary phthisis is promoted by exhaustion and depression, by whatever impairs nutrition and lowers vitality. Insufficient or improper food, excessive work, over-lactation, grief and anxiety, have all been recognised in this relation Diabetes mellitus cannot be excluded from the conditions of depression and ill nutrition which give rise to phthisis. The excavation of the lung which is so common with advanced diabetes is not necessarily, or even generally, tuberculous, but may be associated with caseating pneumonia of other origin; but it appears to be sometimes connected with true tubercle; in such a case the question presents itself whether the microbic invasion is invited merely by the general prostration which the disease engenders or by the local inflammation which is another consequence of it. So far as the diabetic lung is tuberculous, whether the tubercle is connected with lowered nutrition or precedent inflammation, it is clear that the pulmonary lesion is determined not by any special or increased exposure to the germs, but by their being made welcome.

5. *Damp subsoil.*—That a water-logged subsoil is a cause of phthisis has been maintained and disputed. If dry air is one of the conditions antagonistic to phthisis, of which there appears to be no doubt, the contrary condition should have the contrary effect We may therefore be the more inclined to accept Dr Buchanan's conclusions as to the decrease of phthisis consequent on draining Dehydration of the soil, other things being the same, cannot be supposed to have any direct or immediate effect upon the microbes, but probably acts indirectly through the health of the inhabitants making them less ready to give board and lodging to these undesirable visitors It may be that humidity affects the general health injuriously, which the contrary condition restores; or it may be that the decrease of disease is connected with the fact that certain forms of bronchitis are benefited by dryness of air and the bacilli deprived of their breeding-ground.

6 *Overcrowding and insufficient ventilation*—These are among the most effective causes of phthisis; under their influence the disease is doubly promoted, the seed is increased and the soil is fitted. The seed is increased by the multiplication of diseased lungs and the insufficient removal of their products, while the general deterioration of health produced by the vitiated air renders those exposed to it apt recipients of the special morbific agents.

Thus we see in tuberculosis, most obviously when it affects the lung, the assured influence, in the first place, of general ill-health and, in the second place, the scarcely less assured influence of local inflammation The micro-organism, though the primary cause, is of secondary importance. The implantation of the organism, as is clinically indicated, and I may add pathologically demonstrated, in connexion with inflamed tissues or inflammatory products shows pulmonary consumption, in the beginning at least, as a local disease due to local causes Of course, it may arise otherwise as part of a *general infection*, but in either case what we have most to blame is not the bacillus but the reception afforded to it. In the crowding of artificial life the bacilli are scarcely to be avoided. Sometimes, happily for us generally, these "seeds of consumption" fall upon barren soil; at other times they fall upon good ground and bear fruit a hundred-*fold. The conditions which* fit the soil for the seed or the lung for the bacillus have been sufficiently indicated. They are descent from individuals possessing this fitness, the having attained and not over-past a certain age, precedent inflammation, and lowered vitality.

Such considerations gain practical value when we have regard to the ill-success which has hitherto attended attempts to cure phthisis by direct attack upon the bacillus; in other words, by the inhalation of germicides. Could we kill the parasite we might expect to arrest the disease, though we should still have to deal with the injuries already inflicted. But the difficulty is to kill the guest without hurting the host. The micro-organism appears to be more difficult to destroy than the tissues among which it lies The process employed for its detection after death, or out of the body, depends on the power which it has of resisting reagents which are destructive to its environment Whether we shall ever find a way of killing the visitor without doing serious damage to the host is a question for the future—we have not done so yet. The problem is to find a remedy, presumably to be introduced by inhalation, which shall be fatal to the bacilli without being injurious to the tissues. It must be a remedy of discrimination as to what to attack and what to spare. Not corrosive or irritating lest it damage the structures, but by no means inert lest it fail to damage the microbes. It must be capable of good and incapable of harm. We cannot tell what the future may have in store for us—perhaps what we little expect; but at any rate we, or at least I, know of nothing at present which fulfils all the conditions. I have referred only to inhalation. It is so improbable that any destroyer of low life introduced by the mouth or skin should hold its lethal properties in suspense while going the round of the circulation and resume them unimpaired on reaching the bacilli that this mode of conveyance appears even less promising than the direct route by the bronchial tubes.

---

[2] On the Morbid Effects of Alcohol Transactions of the Royal Medical and Chirurgical Society, 1872, vol. lvi. Occasional Papers on Medical Subjects, p 65

Taking leave, then, for the present of the cure of phthisis by germicides we must not ignore the germs altogether, for we may do something by excluding them There is reason to believe that the bacilli, like everything that lives, live only for a time: we may hope to see some of them out. They may leave issue to keep up the race but at any rate we may prevent them from being reinforced from the outside. Purity of air is an obvious desideratum, not only because pure air introduces no bacilli but on the ground that this in certain conditions of temperature and dryness tends to bring about the resolution of many of the minor and limited, but vitally important, forms of pulmonary inflammation which are associated with the development of tubercle and apparently act as its breeding place and procreant cradle. To say that pure air is curative is to express a broad truth in inaccurate language; it should rather be said that pure air does not aggravate the existing inflammatory complications, which impure air does, and leaves the recuperative powers of nature free to work. The process of pulmonary phthisis is a mischievous combination between irritating organisms and irritated organs. To disable one confederate is something in itself and cannot but discourage the other. Our hope, I may even say our assurance, of success in a tangible proportion of cases turns not so much on our shutting out the bacilli, however desirable—an imperfect measure when they have already got in abundantly—still less on our being able to put them to death after they have got in, but on our being able to control the coöperative inflammatory processes and to fortify the tissues against the parasite. The most effective means for this double purpose are climatic, though it is to be regretted that these are not always at the command of everybody.

In these days of applied science and adventurous medicine it is necessary to preach caution lest we have too much thought for the microbe and too little for the man. Let us be guided by experience rather than by experiment. Experience has to do only with results which are matters of simple observation; experiment commonly presupposes a mode of action in which there is much room for error. It is true that there is such a thing as false experience, one form of which rests on wrong diagnosis, curing diseases which never existed; another is the too ready application of the *post hoc propter hoc* inference, attributing recovery to some treatment which had nothing to do with it, a fallacy which rests on an insufficient appreciation of the powers of nature. By these errors quacks are profited and even legitimate practitioners derive advantage. Thus experience, though the best guide we have, requires to be followed with circumspection. In all matters which savour of the experimental and of which man is the subject, or, I may even say, which concern treatment in any way, let us lay to heart the dictum of Hippocrates, self-evident though it may be, "Have two special objects in view with regard to diseases—namely, to do good or to do no harm."[3] To do good is not possible to all, nor is it possible for all to be done good to; but at any rate, we may, all of us and in every case, abstain from doing harm. If we think of dealing with inhalants let us have a reverent care for the air-passages and remember that the lung is vulnerable as well as the parasites which it harbours. Let us admit to the full that fresh air is better than foul air, but nevertheless remember that all patients are not alike, neither do all diseases which bear the same name call for the same treatment. Catarrh and bronchitis are still possible; the old laws which associate them with cold and draught have not been repealed; now as formerly they must be regarded as undesirable superadditions to lungs already unsound, added to which they appear to provide fresh breeding ground for the special organisms of the disease.

In the contest between the man and the microbe it is more to the purpose to back the man than to attack the microbe. The remedies which are most beneficial in phthisis—I may say the only remedies from which we can confidently expect benefit—are those directed to the soil rather than to the seed. They are of two kinds, or rather they act in two modes which may work together to the greater effect. First are agents which fortify the blood and tissues and add to their power of resistance; these are nourishing food, supporting medicines, pure air, and the complex, inclusive, and over-ruling influence of climate. Secondly may be placed influences bearing upon the respiratory organs in particular which discourage the inflammatory processes. Of all such influences suitable climate is the most effective. It would not be easy to analyse this supreme remedy and to give to each quality its due, but among the desiderata are purity of air, dryness of air, and sunlight—several of the essential conditions being brought together in high altitudes where these can be obtained without undue cold. It is obvious that some of these qualities, or some mixture of them, may be beneficial in more than one respect, to the lung in particular and to the system in general. But whichever they influence, whether they suppress inflammatory action or give resistance to the tissues, it is to be presumed that they act upon the human frame proper, not directly upon the parasites by which it is infested.

I have dwelt somewhat tediously upon tuberculosis because this disease illustrates my text in several particulars, but I might adduce instances from totally different disorders in which antecedent disturbance of no specific character appears to have been the starting-point of disease connected with specific organisms. The special microbes seem to be invited by morbid conditions at first unconnected with them. It used to be an article of belief—and no one can say that it is entirely unfounded—that cholera was apt to supervene upon, and seemingly to be induced by, intestinal disturbance at first of no special character. In times of cholera people were warned against food likely to disagree, against strong purgatives, and against the neglect of diarrhœa. Suspicion attached also to cold, and the "cholera belt" was thought to be a protective. In like manner the Anglo-Indian held, and probably still holds, a similar belief with regard to dysentery,[4] one of the accredited causes of which was "the exposure of the abdomen to cold," against which the prudent carefully guarded themselves. Let us not be too keen, in our modern wisdom, to sneer at these issues of ancient experience. We know that both cholera and dysentery, cholera always and dysentery sometimes, are due to special micro-organisms but it may be suggested by way of reconciling old saws and modern instances that the antecedent disturbance in this case, possibly of the nature of catarrh of the bowel, not at first specific or microbic, created a suitable nidus for the specific germs and so determined an attack which, but for the accident of cold or intestinal irritation, would not have taken place.

Some of the preceding considerations may be provisionally applied to cancer. I say "provisionally," for with regard to this disease we are still in the dark. No parasitic organism has yet been found, though the growth displays in some respects a parasitic character. All that we can see is a vicious overgrowth, essentially of epithelium, which extends at the expense of neighbouring tissues, is conveyed by vessels, particularly lymphatics, and displays a tenacious vitality which goes a long way to account for its habits. Many years ago I published[5] a case in which the contents of a malignant cystic tumour escaped into the peritoneal cavity with the result that after death, which was not long delayed, the peritoneum was found to be studded with cancerous accretions like mulberries, which were superficially attached as if they had lighted upon the surface, not developed in the substance. I could recall o[illegible] observations similarly illustrating the translation of ca[illegible]ncer by contact a mode of morbid action beyond doub[illegible] as affecting adjacent structures belonging to the same [illegible] individual though not equally evident as between org[illegible] belonging to different persons. The tenacity of [illegible] which enables cancerous [illegible]ation of [illegible] which enables [illegible] particles to flourish after having been cast loose from their original attachments suggests something parasitic though it does not prove it. A parasitic origin is also hinted at by the apparent habit of cancer to be repeated in certain districts and dwellings Regarding cancer from the hypothesis of an origin in some living thing brought from without, it could be argued that, as with tubercle, the malignant microbe is not impartial in its choice of person and bodily place, that though scattered as we must suppose indiscriminately it selects individuals inheriting a certain proclivity, who have attained, and not over-passed, a certain age, and who have been depressed by grief or anxiety As to locality it chooses situations of former injury as declared by cicatrices and other results of bygone accident. These considerations show that if cancer has a special germ a special fitness of the recipient body is needed to give it effect.

[3] Epidemics, Book I., p. 360

[4] Ziem[illegible] ..., vol. i., p. 562.

[5] Case of Colloid Cancer, [illegible] illustrating the Independent Vitality of the Cancer Cell, Transaction[illegible] of the Pathological Society of London, 1681, vol. xii., p. 92.

As has been said of the bacilli of tubercle so of the organisms of constitutional disease in general they are out of our direct reach, but we can in some instances get at them indirectly by making the blood and tissues unfit for their support. The antitoxins provide one of the most remarkable chapters in modern discovery and an illustration of the universal law that the seed is impotent without the consent of the soil. The bacillus, say of diphtheria, gives exit to something which is prohibitive of the diphtheritic process, and this not by destroying the germs of the disease—for the bacilli of diphtheria will grow and flourish, so I am assured, in its antitoxic serum—but by in some way, indisposing the body for their entertainment. The antitoxin placed under the skin enters the blood and reaches the tissues; how far it reaches the bacilli is not clear but it is apparent that if it did reach them it would do them no harm. The immediate effect of the antidote is, to all appearance, upon the blood and tissues, not upon the bacilli, these become atrophied, not, as it seems, because they are poisoned by the antitoxin but because the blood and tissues are no longer suited to their support. Here we may pause; much remains to be learned but at any rate we have learned that in our theories of zymotic disease we must have regard not only to the germs but their reception. It is to be hoped that we shall soon know more about the antitoxins and become able to employ them to further advantage. They have accomplished something and promise more. Tubercle comes within the probability of control by their means and even cancer within the imagination of it

I may end, as I began, with the recognition of the universal truth "*omne vivum ex ovo.*" By all means let us exclude the germs of disease; if we can do so perfectly we shall be perfectly free from the diseases which they engender. But where, as too often happens, this is impossible it remains for us to accept the inevitable and to deal as best we may with the germs or their environment. Our encouragement so far has been to act upon the soil rather than directly upon the seed and, so far as our attempts at cure go, to place our chief hopes on antitoxins rather than on germicides. It seems presumptuous to speak of *cure* but yet the action of the diphtheritic antitoxin presents itself as so distinctly antidotal that the term may be excused if not justified.

I have reached the end of my sermon and I think that you will admit that I have not wandered very far from my text. If I have taken up your time with old commonplaces it is because old truths are apt to be pushed aside and forgotten in the attractions of modern science with its rapid movement and ever-changing phases. It may be as important to hold by old truths as to acquire new ones, or what we for a time accept as such. In these days of bacteriology and the magnification of germs, necessary and progressive as such researches are, it is well to be reminded that all questions of propagation, whether of animals, vegetables, or diseases, depend on the mutual adaptation of the germ and its situation. Most of the transactions which occur under the sun can be looked at from two points of view—the donor and the recipient, the attacking and the attacked, the seed and the soil One who desires to see the whole of what is before him must have regard to both

---

PLAGUE IN A ZOOLOGICAL GARDEN.—It was mentioned in THE LANCET of April 26th, p 1219, that plague had reappeared in Sydney and had even attacked some of the animals (wallabies) in the zoological garden. A Reuter's telegram of April 30th states that 19 animals have died in the zoological garden from this cause.

EMBALMING THE DEAD.

By J. G. GARSON, M.D Edin,

ADVISER ON IDENTIFICATION TO THE HOME OFFICE; MEDICAL REFEREE UNDER THE WORKMEN'S COMPENSATION ACT.

THE simplest means of preserving the dead is perhaps that employed by some savage races even to the present day of exposing the body after death to the influence of the sun and the air till the aqueous fluids of the tissues are dried up by evaporation. Such a method is only possible of application in those limited areas of the world where climatic conditions favour rapid desiccation and even in these places would not be available were the inhabitants collected together in towns of any considerable size. The application of what may be termed natural methods not being generally practicable, artificial processes have been resorted to from early times for the conservation of the body after death and practised with so much success that the art of embalming is very generally believed to have reached its perfection as far back as the time of the early Egyptian dynasties and to have been to a great extent, if not altogether, lost in modern times. It is not, however, the art that has been lost but the practice of it which has become in many places well-nigh discontinued Our knowledge of the anatomy and physiology of the body as well as of the nature of chemical action and of chemical compounds gives us the means of practising the art in a much more thorough manner than was possible in earlier times. And although the methods employed by the ancient Egyptians and other races were effective, as shown by the numerous well-preserved mummies which we are familiar with in our museums, yet they cannot but be regarded as extremely crude, and the results were only obtained after an expenditure of much time and labour, 70 days being, according to Herodotus, the usual period required for each of the three processes which he has described. The Egyptian plan of procedure was briefly as follows: the body was first prepared by the removal of the abdominal and thoracic viscera and of the brain; it was then subjected to a process of pickling by immersion for a period in preservative fluid, after which various powdered herbs, resinous or bituminous material, &c., were introduced into the cavities, and finally the whole body was swathed with bandages saturated in preservative solution. By the modern methods the whole procedure is much simplified and expedited, requiring but a few hours to accomplish The preservative fluid is distributed directly to all parts and tissues of the body through the ramifications of the vascular system, just as the nutritive elements in the blood were conveyed during life. Preliminary removal of the viscera is unnecessary—in fact, renders the operation so much more difficult that in cases where post-mortem examination of the organs is wanted it should be postponed if possible till after the embalming process has been completed.

At the present time embalming is most frequently resorted to for the purpose of enabling the body to be kept uninterred longer than would otherwise be possible without detriment to the living, as when death occurs at sea or at a distance from the intended place of sepulture, or when friends of the deceased have to come from a distance to attend the obsequies In such instances it is only required as a temporary measure to postpone the occurrence of putrefactive changes for a longer or shorter period. But it is also required sometimes for the permanent preservation of the body, as when interment is to be made in a vault or mausoleum In these cases embalming should always be practised and should be done most thoroughly, not only for the purpose of securing the object desired by the relatives of the deceased, but especially to render impossible as far as may be the generation of any noxious products which emanating from the body, might give rise to an insanitary condition of the place of sepulture and thereby be a cause of danger to the living at some subsequent period

In the practice of embalming it is not enough that the process adopted, which must be varied according to the requirements of each particular case, shall be efficient for the prevention of putrefaction and decomposition for a longer or shorter period or permanently. When the body is to be inspected by relatives some time after death has occurred, or is to "lie in state" for a period, the preservation of as placid and lifelike a condition of the features as possible is undoubtedly a great desideratum and has carefully to be considered in selecting the process of embalming which is to be employed. Some very efficient preservatives cause rapid alteration of the face from shrinkage and their action in this direction has to be retarded or modified in cases where the natural appearance requires to be maintained. Again, in some cases the after-death appearance may be such as to make it desirable to impart a more lifelike aspect to the face than it has assumed. These several objects may readily be attained by the proper use of the various chemical products which modern science has put within our reach.

From what has been stated, and from that which is to follow, it will be seen that embalming is not a matter which should be relegated to the undertaker or someone employed by him to see to, as is too often done with unsatisfactory results. If it is to be practised successfully it calls for as much knowledge, judgment, and skill as does the performance of a surgical operation and therefore it should always receive the direct attention of the qualified medical attendant of the deceased.

In temperate climates the best period to select for the process of embalming is about 24 hours after death, when, as a rule, rigor mortis has nearly passed off and the tissues have become relaxed but no marked signs of putrefaction have begun to show themselves. The presence of putrefactive changes is not, however, any bar to the operation by which not only will the further progress of these changes be at once stopped but the parts which have become affected will be greatly improved, if not restored to their natural appearance.

Having informed himself as to the purpose for which the embalming is required the operator has to determine upon his plan of procedure and the composition of the solutions to be used—both points of considerable importance.

As regards the plan of procedure, whether the operation is undertaken for temporary or for permanent preservation of the body it should include the introduction into the tissues through the vascular system of a suitable preservative fluid and the external application of the same to the surface of the body, the latter being necessary to counteract the tendency which the epidermis has to separate from the dermis. Any gas or fluid which may have accumulated in the abdomen, thorax, and elsewhere should be removed and some preservative fluid injected in its place To enable the different parts of the process to be performed with facility the body should be placed on a long narrow table such as is used for ordinary surgical operations. If, however, this is not available and nothing better can be obtained the lid of the shell or coffin, supported on trestles or otherwise at a convenient height for the operator, may be utilised for the purpose. The operation should not be attempted with the body lying on a bed or in the coffin. The introduction of the preservative fluid into the vascular system is effected by exposing and opening one of the larger arteries situated near the surface and inserting into it a metal cannula to which is attached a tube through which the fluid is to be injected. The artery sometimes selected for this purpose is the brachial in the upper third of the arm, but in the majority of subjects the femoral in Scarpa's triangle is more suitable and is perhaps the artery most frequently chosen. In my experience, however, it is preferable in all cases where the body has to be thoroughly embalmed to select the abdominal aorta just below the umbilicus. At this spot it is easily reached by a median incision of about seven or eight centimetres long through the anterior abdominal wall, from which, in the normally collapsed state of parts after death, it is separated only by a short interval. The advantages gained by selecting this artery are its large size and the variety of other purposes served by the external incision made to expose it, whereby the operation is facilitated and rendered more effective. Thus, while the preservative fluid is entering the artery the condition of the inferior vena cava, which lies immediately to the right of it, can be seen, and if the flow of the injection in the capillaries be impeded by venous congestion this can be at once relieved. Again, any fluid or gas in the abdomen and its hollow viscera or in the thorax can be evacuated directly or by means of an aspirator needle introduced through the opening and preservative solution injected directly into them. If the opening be neatly sutured afterwards little more external trace of it will be visible than would have remained if the femoral had been selected.

The method of introducing the preservative fluid into the artery selected requires the careful consideration of the operator. The tissues being now dead matter and therefore no longer endowed with vital properties are not in the same condition as they were during life. The blood-vessels are less able to bear a strain equal to that exerted upon them by the normal blood-pressure during life; this is particularly the case when they are in an atheromatous condition, as frequently happens in old people, or when the tissues in which they are embedded are softened or broken down by disease and are consequently unable to give them the usual amount of support. The resistance to the establishment of the flow of the preservative fluid through the dead body is also a factor never present in the living and the risk of rupture of the blood-vessels during the process is proportionately increased according to the force exerted to propel it and the rate at which it is made to travel, particularly if the pressure be suddenly or unevenly applied. A rent taking place from any cause in an artery of even medium size is a serious impediment to the successful distribution of the preservative fluid and generally gives much trouble. In order to get the best results, therefore, it is of great importance to inject the preservative fluid with as low and continuous a pressure as possible. This being so it is obvious that the syringe ordinarily used to inject bodies for the dissecting-room is not suitable for the purposes of embalming, firstly, because there is no means of gauging the pressure which is being exerted by it, except the very rough one of the feeling of resistance offered by the fluid in the syringe to the onward progress of the piston; and in the second place, because it is impossible to keep up a slow and regular pressure with such an apparatus for the period necessary to get the fluid properly diffused through the tissues of the body, owing to the muscular fatigue which sooner or later affects the arms of the operator, causing him to act spasmodically. The continuous and regular pressure required is best obtained either by compression of the air above the surface of the preservative fluid placed in a closed receptacle connected at its base by a tube with the artery through which it is to be introduced into the body, or by utilising the force generated by the fluid itself in flowing from the receptacle placed at a higher level to the artery situated at a lower level. Each plan has its advantages and disadvantages, and the adoption of the one or the other must be determined upon by the operator according to the conditions under which the operation has to be performed. The requisite air-pressure is obtained by pumping atmospheric air into the receptacle containing the preservative fluid by means of bellows or a hand pump such as that used for the inflation of pneumatic tyres, worked slowly and regularly. To obtain enough hydrostatic pressure all that is necessary is to raise the vessel containing the fluid, which should be open at the top and have the tube attached to an opening at the base, till the resistance of the tissues is overcome and the fluid flows slowly through the blood-vessels. Whether the one method be adopted or the other, there should be introduced in the course of the stream of fluid as it passes from the container to the artery a gauge of some kind to indicate the force with which the preservative is entering the body. For this purpose a simple glass U-tube containing mercury and attached to an upright support on which is marked a graduated scale of units of pressure acts as satisfactorily in practice as any of the more complicated and expensive forms of fluid-pressure gauges. To enable the operator to observe the rate at which the fluid is entering the system the vessel containing the preservative fluid should be graduated. It is important for the operator to watch both the rate and the pressure which the fluid is entering the system because a sudd increase of the former with decrease of the latter is a certa indication that rupture of one or more of the arteries h taken place and that the fluid is being extravasated into t surrounding tissues or into some cavity, instead of circulati through the vascular system as a whole.

The composition of the preservative solution to be us will to some extent depend upon the circumstances which the operation is performed and the chemicals whi are available, as well as on the predilections of the operat In every case, however, it should be sufficient in quanti and energetic enough in its direct action on the tissues prevent putrefaction of the body for the period requir whether that be short or long, and at the same time it mu be sufficiently fluid to pass into the minute blood-vess and to percolate through the walls of the capillaries into t surrounding tissues which it must thoroughly permeat On the other hand, it must neither be too strong nor of su a nature as to cause immediate hardening and contraction of the walls of the blood-vessels during its passage through them, otherwise imperfect preservation of the body will be the result. As the presence of water in the tissues, as well as a supply of free oxygen gas, is essential for putrefaction, and as the body contains sufficient moisture for the spontaneous occurrence of that process, the preservative injected should likewise possess the power of attracting to itself and absorbing the watery constituents present, and, by subsequent reduction, cause desiccation of the tissues. The rapidity with which this latter process is to take place has generally to be regulated by the time of closure of the coffin, as it causes shrinkage of the features. Judgment and knowledge of the materials used are therefore needed, not only in selecting the proper chemicals to get the desired results, but also in determining the proportions in which they are to be mixed.

The base of the injection fluid should be a substance which will combine chemically with animal matter and confer on it the power of resisting putrefaction to a high degree, it should also absorb and fix ammoniacal gas, form insoluble compounds with azotised organic principles, and be readily soluble in the vehicle used which must of necessity form the bulk of the injection. The substances which possess these properties to the fullest degree and are the most convenient to use are perhaps bichloride of mercury (corrosive sublimate), chloride of zinc, and chloral, and of these the first is upon the whole the best for purposes of embalming and the least expensive. As the introduction of more water into the tissues than already exists is highly undesirable for the reason previously stated, the use of that liquid as the vehicle of the injection is to be avoided as far as possible. In alcohol we possess a fluid peculiarly well suited for the purpose, being of itself a good preservative, having a great attraction for water which it readily abstracts from animal tissues, and therefore in every way a valuable adjuvant to the base, as well as a most effective solvent and reducer, properties which it is very desirable the injection fluid should possess. To use rectified spirit for this purpose would be unnecessarily costly, when the best methylated spirit is equally as efficient and quite good enough in all ordinary cases.

The composition, therefore, of a good preservative solution for the blood-vessels should consist essentially of bichloride of mercury or some similarly acting salt and methylated spirit, and this may also be used for external application and for injection into the cavities and hollow viscera. Two grains of corrosive sublimate in each ounce of injection fluid (1 part in 220) will be found generally to be the best strength to begin injecting the blood-vessels with, but the strength of the solution should be somewhat increased during the later stages of the process, even to four grains to the ounce of fluid. The bichloride may be readily dissolved by rubbing it in a mortar with some spirit in which it is soluble to the extent of one in seven. An injection fluid composed only of the mercury salt and spirit dries and contracts the tissues rapidly if evaporation be free. It is therefore often necessary to delay this result by adding some glycerine as a corrective. The quantity of glycerine added for this purpose should not exceed one quarter of the bulk of the spirit used and in most cases much less will suffice. The amount of preservative fluid required for a body will vary with its size but may be approximately stated to be about two gallons or nine litres for an adult male and about five litres for an adult female. The formula of the injection fluid for an adult male will therefore work out as follows: bichloride of mercury, from 640 to 900 grains—or, say, from one and a half to two ounces (from 42 to 57 grammes); glycerine, from 10 to 80 ounces (from 0·25 of a litre to 2·25 litres); and methylated spirit to two gallons (nine litres). This will give some idea of the quantity of the chief ingredients which the operator will have to provide himself with for the operation. Some more of the fluid will be required for injecting into the hollow viscera and into the body cavities and likewise for applying externally. If the prevention of putrefaction is required only temporarily less preservative need be used; thus in cases where putrefaction has set in unusually early, as sometimes occurs in hot weather in England or as a sequence of death from certain diseases, less than half the above-mentioned quantity of injection fluid will suffice. The result of injection of the blood-vessels with the preservative fluid just given will be to produce a pearly whiteness of the skin and the expression of the countenance will, except in this respect, be natural. To give a more life-like colour to the countenance a small quantity of some soluble red colouring matter may be added to the injection fluid, such as rosaniline or erythrosine, but this must be done very carefully, as effects other than those desired may be produced.

Chloride of zinc has long been used for purposes of embalming and is an excellent preservative, but a much larger quantity of it is required than of corrosive sublimate. Hitherto it has been usual to dissolve the chloride of zinc in water and sometimes to add alcohol to the solution, but in several formulæ the latter is omitted altogether. The strength of solution recommended differs widely; thus, for a body weighing 100 pounds Richardson used to inject five pints of a saturated solution with one pint of spirit added to it. Reeves recommends the injection of as much as the blood-vessels will hold of a solution containing two-thirds of a part of zinc chloride to one part of distilled water, which is somewhat weaker than the liquor zinci chloridi of the British Pharmacopœia, while a third formula gives eight litres of a solution containing one part of zinc chloride in three parts of water. By the first of these formulæ 15¼ pounds of zinc chloride are required (its solubility being 10 in 4 of water) in the six pints of solution; by the second, assuming that two gallons will be taken up by the blood-vessels, 13¼ pounds; and by the third, in the eight litres there would only be six pounds. The quantity of chloride of zinc used for injection into the vascular system in a case of complete embalming should certainly be from 12 to 15 pounds. This should be dissolved in methylated spirit, in which it is freely soluble and in many cases some glycerine may with advantage be added to the solution. As this injection rapidly hardens the tissues it is well to begin with a weaker solution and gradually to strengthen it during the process.

Some authorities prefer to use a preservative composed of hydrate of chloral as the base. With spirit as the vehicle and adjuvant such a solution is very effective in drying and hardening the tissues and quickly produces mummification. It should be used in the proportion of one part of chloral in eight parts of injection fluid, which may with advantage also contain some glycerine to prevent too rapid desiccation. From two to three pounds of chloral will be required for an adult male body. The solution first injected should not exceed 10 per cent. in strength, but afterwards the strength may be increased to about 15 per cent.

The instruments and appliances required for embalming are a bistoury; dissecting forceps; an aneurysm needle; a blunt hook; artery forceps; cannulæ of different sizes fixing into a stopcock-tube to the other end of which a piece of indiarubber tubing two yards in length is attached; a graduated bottle holding one gallon (about four litres) with a circular opening close to the base, into which is inserted a tightly-fitting rubber cork perforated by a stopcock-tube to which is fixed the other end of the rubber tube, and with a moderately wide neck into which a rubber cork perforated by a metal tube fits tightly; a piece of rubber tubing to fix over the upper end of this last tube about a foot in length; a U-shaped pressure-gauge attached by rubber tubing to the stem of a T-piece, the horizontal arms of which are to be inserted into the long tube at about two feet from the cannula; a double-action aspirator syringe with a somewhat curved, sharp-pointed cannula of good size and at least six inches in length; a pneumatic pump; scissors; suture silk and needles; a good-sized painter's brush; a bottle with three ounces of strong liquor ammoniæ; some narrow tape; sponges; cotton-wool; bandages; and some antiseptic ointment for the operator's hands. It is also desirable to have at hand a small post-mortem case, as some of the instruments which it contains may be required.

The cannula which I have found to be most convenient for inserting into the artery, whether that be the abdominal aorta or the femoral, is T-shaped, consisting of a right and a left half fitting closely together down the centre of the stem over which the stopcock-tube is passed to hold the two halves firmly against one another. One half of the cannula is inserted up the artery, the other in the opposite direction, and when they are united the injection will flow simultaneously both upwards and downwards. This obviates the necessity of introducing two cannulæ with double attachments to the rubber tube and a much smaller opening in the artery is required. The size of the cannula for the abdominal aorta should be from 15 to 20 millimetres in diameter, but for the femoral it should measure only about eight millimetres.

The apparatus described is designed so that it can be used for injecting the preservative fluid either by gravitation or by air-pressure, as the operator may decide, and he may at once change from the one method to the other at any time during the course of the operation, without interfering with any of his previous arrangements, by connecting or detaching the aspirator syringe or pneumatic pump and the rubber tube affixed to the tube through the cork in the neck of the bottle. The preservative solution to be used should have been previously prepared in as concentrated a form as possible, so that it only requires to be diluted with additional spirit at the time of the operation to bring it down to the strength previously indicated and so make it ready for use.

The plan of procedure having been determined and the preservative fluid to be used being ready the operator, after seeing that he has been supplied with hot and cold water and the proper utensils, such as basins and slop or toilet-pails, also towels, &c., should proceed to lay out his instruments and to set up his apparatus and charge it with preservative fluid; lastly, the body is to be placed on the operating table. As a preliminary to the operation, especially if rigor mortis has not quite passed off, the limbs should be gently flexed and then extended to relax the muscles. The artery is next to be exposed and opened by a vertical incision and the double cannula introduced fixed and secured by ligatures. Before fixing the tube from the reservoir to the stopcock-tube on the cannula the procedure recommended by Richardson of inserting into it the nozzle of the syringe or pneumatic pump previously charged with ammonia vapour and forcing some of the latter into the arteries certainly seems to facilitate the flow of the preservative solution when the injection is begun and may with advantage be followed. The tube having been filled with fluid by turning on the tap at the base of the reservoir, it is attached to the free end of the stopcock on the cannula and the solution is permitted to enter the vascular system. If the gravitation method of injecting be adopted the reservoir has now to be elevated till the fluid has sufficient "head" to pass into the system, and the pressure-gauge and index is to be watched till the solution is nearly exhausted, when the reservoir should be replenished with stronger solution than that first used. Should the operator adopt the pneumatic pressure method the nozzle of the pump or syringe is inserted into the tube attached to the cork in the neck of the bottle or reservoir, and he proceeds to pump air into the latter till he sees by the index that fluid is entering the arteries; this being effected he has to maintain the pressure indicated by the gauge as the quantity of solution in the reservoir diminishes. If this latter method be selected the reservoir requires only to be placed upon a table about level with the body. In default of a sufficiently high resting-place being obtainable to get the necessary pressure for the first method a combination of the two methods should be practised. After a few litres of solution have passed into the system, if everything has gone on satisfactorily, the skin will begin to present a mottled appearance, first observable in the face, which will gradually begin to look fuller and more life-like and perhaps even puffy about the eyelids, the superficial veins of the body will become more pronounced as they become charged with blood, and as the white mottling spreads and adjacent patches coalesce. At this stage it is desirable to examine the inferior vena cava through the abdominal opening and to tap it if distended to relieve the venous engorgement and resistance. As more injection fluid passes into the system the body will become quite rigid and the skin white and parchment-like, unless the solution contains sufficient colouring matter to give it a pinkish hue. The injection will gradually pass in more slowly, although the gauge indicates that the former pressure is being maintained, and finally stop flowing, showing that the vascular system has been fully charged. The stopcocks may then be turned off for a time and the solution already introduced permitted to diffuse itself equally in the tissues. At the end of five or six hours an attempt may be made to introduce some more solution, if considered desirable, but this is not often necessary unless rigidity has not been established, which seldom happens. Meanwhile the operator proceeds to deal with the thoracic and abdominal viscera. The diaphragm should be punctured with the aspirator needle, care being taken not to injure the heart or lungs in so doing, any gas present should be allowed to escape, and some strong preservative solution should be jected. The same procedure should be adopted with the [illegible]h, the bladder, and the intestines; the last-named will require to be punctured at two or three places. Finally, some solution should be injected into the peritoneal cavity, the nasal cavity, and the mouth. If the superficial veins are still engorged it is desirable to empty them as far as possible by rubbing them in the direction of their main trunks and to inject some solution of the first used strength into them from their distal extremities.

The external application of preservative has next to be done. For this purpose a strong solution of bichloride of mercury and spirit should be prepared and rubbed well into the skin of the head about the roots of the hair with a painter's brush, and the whole of the body should be painted over several times with a mixture of one part of the concentrated sublimate solution to about six or eight parts of glycerine.

If no further injection of the vascular system be required ligatures may be placed round the artery immediately beyond each end of the double cannula and tied. The cannula is then to be removed and the edges of the external opening are to be brought together neatly and sutured closely with fine silk. The operation being completed the body is to be replaced in the shell along the bottom of which should previously have been arranged a thick layer of sublimate wood-wool.

In the foregoing description it has been assumed that the condition of the body has been favourable for the operation and that no hitch has occurred during its performance. Things do not always run smoothly, however, and the operator must be prepared for less satisfactory conditions being present and for accidents happening, and he must be ready to meet emergencies just as he would do should they occur in the course of a surgical operation he was performing. It is only possible here to mention some of the complications which may confront him and render the operation more difficult.

Perhaps the most frequent complication which occurs in the course of an ordinary injection operation is rupture of an artery. It generally takes place in the thorax or the abdomen and is usually the result of disease of the vessel or organ in which it occurs. In such cases one or other or both of these cavities must be opened in the manner to be described presently when a post-mortem examination of the organs has to be combined with an embalming operation and the ruptured vessel secured by ligature or otherwise; in some cases the organ in which it is situated must be removed. Rupture of a vessel inside the skull is of little consequence, that being a closed box and strictly limited in capacity. In other parts of the body, also, the vessel can more or less readily be got at and tied and the rupture does not materially interfere with the operation. Such accidents are fortunately rare when the pressure with which the solution is introduced into the system is kept low.

The most troublesome cases to deal with are decidedly those in which general anasarca is present. Before attempting to inject preservative fluid into the vascular system in these cases the dropsical condition must as far as possible be got rid of, otherwise the solution will not flow through the vessels into the tissues, owing to the coagulation of the albumin in the serum which immediately results from contact with the preservative, whether that be corrosive sublimate or chloride of zinc. The best course to pursue in these cases is to begin by making the incision in the abdominal wall to expose the abdominal aorta, then, if ascites be present, the fluid contained in the abdomen should be syphoned out with indiarubber tubing. While this is being done the limbs should be elevated as much as possible and tightly bandaged from their distal extremities upwards towards the trunk with a broad indiarubber bandage, such as is sometimes used in the treatment of callous ulcers. The bandaging may with advantage be carried onwards beyond the limbs and made to include the greater part of the trunk. The artery should be opened for the insertion of the cannula and in most cases the inferior vena cava should also be incised and punctures made where necessary to let the serous fluid escape; the thoracic cavity should likewise be tapped from the abdominal opening by puncturing the diaphragm, and any fluid which it contains should be removed. After the condition of the body has been improved as much as possible the injection of the preservative solution may be proceeded with. It will be found generally that the injection has to be made under considerably higher pressure than is ordinarily required and the risk of rupture of a blood-vessel is correspondingly increased in consequence. Should much difficulty be met with in getting the injection to enter the system it may be necessary, attacks of profuse hæmaturia for eight years. The kidney was removed by the lumbar route and the patient made a good recovery.—Mr. F. V. Milward read a paper on Localised Intra-peritoneal Suppuration and its Treatment by Drainage which was illustrated by a series of wax casts of the various intra-peritoneal spaces.—Dr. McCardie read a paper on a case of Faintness and another of Vomiting after Operation under Ethyl Chloride Narcosis.

GLASGOW SOUTHERN MEDICAL SOCIETY. — A meeting of this society was held on March 20th, Dr. John Stewart, the President, being in the chair.—Professor McCall Anderson opened a discussion on the Curability of Phthisis Pulmonalis. He spoke approvingly of the use of tuberculin and said that he had long been an advocate of the open-air treatment. He believed in the efficacy of a residence in a high mountain valley where pure air could be breathed. Sanatoriums for the treatment of phthisis ought to be built on sites readily accessible, on dry and porous soil, and in an atmosphere as pure as possible. He thought that the results of the treatment of pulmonary consumption in sanatoriums were most encouraging.—Dr. George Middleton remarked that no doubt many cases of phthisis after treatment in sanatoriums gained flesh and weight, but the physical signs often remained the same. No matter how early in the course of the disease he was enabled to treat pulmonary phthisis he was always apprehensive as to the result. In treatment he advocated fresh air, cod-liver oil, and good food, and he could recall to mind many cases of phthisis that recovered by this means of treatment. He was of opinion that the injection of tuberculin was not without risk.—Dr. James Hamilton remarked that he had seen many cases of phthisis pulmonalis in which recovery had undoubtedly taken place.—Dr. Charles E. Robertson said that he did not think that a cure was a common result of treatment, although improvement in the patient's condition was occasionally seen. He welcomed sanatoriums, not because of the curative effects of the treatment therein, but because they were a means of preventing the spread of pulmonary phthisis.—Mr. L. Burges said that he had seen cases in which the tubercle bacilli were found and in which a cure resulted under treatment.

BIRKENHEAD MEDICAL SOCIETY.—A meeting of this society was held on March 14th, Dr. J. Pinkerton, the President, being in the chair.—The minutes of the previous meeting were read and confirmed.—Dr. White showed a specimen of Advanced Atheromatous Disease of the Aorta and gave notes of the case.—Dr. Edgar Stevenson read a paper on Tinnitus Aurium and Chronic Deafness and gave a demonstration of a New Method of Treatment.—Mr. H. L. Pearson, Dr. Wilkinson, Dr. Harrington, and Dr. Lambert joined in the discussion which followed and Dr. Stevenson briefly replied.

Reviews and Notices of Books.

Études Anatomiques sur les Grossesses Tubaires. Par le Dr. A. COUVELAIRE, Ancien Interne des Hôpitaux, Chef de Clinique Obstétricale à la Faculté de Médecine de Paris. Paris: G. Steinheil. 1901. Royal 8vo, pp. 160, 21 Plates. Price 12 francs.

THESE researches of Dr. Couvelaire are of great importance. As he justly remarks, the true anatomy of tubal gestation can only be studied by the examination of early specimens in which no secondary changes have occurred. He has been able to investigate 14 such cases. In seven of these the ovum was attached in the isthmus and in seven in the ampulla of the tube.

This monograph includes a study of the topographical anatomy of the gravid tube beyond the tubal sac; of the anatomy of the ovum in the tubal sac; of the attachment of the ovum to the tubal wall; of the free pole of the ovum—viz., the area corresponding to the reflexa; and some researches upon the anatomy of tubal rupture. The cases are recorded in full and there are several very good photo-engravings.

The author finds no evidence of the presence of any preceding salpingitis in his specimens and does not think that disease of the tube plays any important part in the etiology of tubal gestation. The changes in the wall of the tube, he considers, are produced by the presence of the ovum and do not, as has been maintained by other writers, precede it. He has been unable to find any changes in the opposite tube analogous to those described by Webster and others and he concludes if such changes do occur that they must be a matter of some rarity. In all his cases the intensity of the changes in the tubal wall are directly proportional to its nearness to the site of the ovum and affect all the tissues of the tube. In his study of the anatomical changes at the site of the attachment of the ovum he has not been able to find anything corresponding to the spongy layer of the decidua as described by Webster. The intervillous spaces are separated from the wall of the sac by an irregular layer of cellular elements termed the external capsule of the ovum and which Dr. Couvelaire thinks is entirely of fœtal origin. Between this external capsule and the wall of the tube itself there is no very clear limit. In the immediate neighbourhood of the ovum there is marked infiltration of the wall of the tube with leucocytes. Examination of the free pole of the ovum shows that it is covered by a membrane composed mainly of fibrin and large cells like those found in the external capsule. This covering, which also appears to be formed entirely from fœtal tissues, can only be termed a decidua reflexa from its topographical anatomy, as it does not appear to fulfil any of the functions of that layer of the decidua. Attached to the external surface of this pole of the ovum, and in the later stages of development considerably atrophied and compressed, are some of the fringes of the mucous membrane of the tube.

In a study of the anatomical changes associated with rupture of the sac Dr. Couvelaire points out the important part played by the invasion of the wall of the tube by the fœtal villi, the resulting rupture of the vessels, and the occurrence of interstitial hæmorrhages with consequent thinning of the wall at the seat of ultimate rupture. The book is a valuable contribution to the study of tubal pregnancy and gives a clear account of some very careful and good work.

Das Wachstum und die Verbreitungswege des Magencarcinoms. (The Growth and Mode of Extension of Carcinoma of the Stomach.) By Dr. ROBERT BORRMANN. Jena: Gustav Fischer. 1901. 8vo, pp. 400, 16 plates and 21 figures. Price 16 marks.

THIS important monograph by Dr. Borrmann is based on work done by him in Professor Ribbert's pathological institute, the material being supplied by Professor Mikulicz. No fewer than 63 specimens of excised carcinoma of the stomach were carefully and thoroughly examined. The work was chiefly undertaken with a double object in view—namely, to prove whether the new growth really increases and multiplies out of its own proper elements, or whether the neighbouring tissues undergo transformation into tumour tissue and so add to the tumour. It may be stated at once that Dr. Borrmann's researches lead him to the conclusion that there is only one mode of growth in gastric carcinoma and that is by the increase of its own elements without the neighbouring tissues taking any part in it.

The subject matter of this book is arranged under (1) a special part in which full details of the cases are given and (2) a general part which is again divided into pathological and clinical sections. Two tables are appended giving the clinical and other details of the cases and finally the illustrations in the plates are explained.

As regards the extension and spread of carcinoma of the stomach the author says that it is generally well known that the carcinoma spreads through the layers of the stomach (with the exception of the mucosa) by the lymphatic spaces and vessels. Nobody, however, seems to have thought that the carcinoma cells may multiply in the lymph channels of after as much preservative has been introduced as can be got into the arteries, to supplement this by making subcutaneous injections into the muscular and cellular tissue at numerous points over the body as well as into the cavities In bad cases it is perhaps better to use hydrate of chloral dissolved in alcohol and a little water, or a solution of formic aldehyde, instead of corrosive sublimate or chloride of zinc solution, as being less liable to produce immediate coagulation of the albumin of the serum infiltrating the tissues and clogging of the blood vessels.

When death has resulted from the bursting of an aneurysm in the thoracic or abdominal cavity the injection should be performed from the ruptured vessel which has to be exposed for the purpose.

A post-mortem examination of the viscera as well as the preservation of the body by embalming may be required In this case the injection of the vascular system and the external application of preservative should, if possible, be done first, the application of preservative solution to the visceral cavities being postponed till after the post-mortem examination has been made. The latter should not take place before the lapse of 24 hours after the injection of the vascular system. But circumstances sometimes demand that the post-mortem examination shall be done first before any chemicals have been introduced into the body In this event the best plan is to begin by making one long median incision from the top of the sternum to the pubes, then to divide the sternum longitudinally, and forcibly to separate the thoracic walls as far apart as possible, fixing them in this position by means of two pieces of wood placed at each end of the sternum The space thus obtained is limited, but by dexterous manipulation it will be sufficient to enable the operator to reach the heart and lungs and to remove them. The aorta and vena cava should be divided close to the heart, a thread having previously been passed through each and the ends brought to the surface of the thorax so as to facilitate the subsequent recovery of these vessels. The trachea should be divided just above its bifurcation, in doing so care must be taken not to injure any of the blood vessels of the neck. The nerves and other structures having been divided, the heart and the lungs are then to be removed carefully without disturbing their surroundings more than is absolutely necessary After their examination has been completed they should be washed and immersed in preservative solution The œsophagus and rectum are then to have double ligatures placed round them the former just above the stomach, and to be divided between the ligatures, the digestive tract with the pancreas and the spleen and then removed, the arteries having been ligatured one by one as they are divided. A ligature should be placed on the inferior vena cava above and below the liver and on the other vessels, these are then to be divided between the ligatures and the liver and the latter removed The kidneys are to be removed after their vessels have in like manner been ligatured The examination of the viscera having been completed they are to be placed in preservative solution for some hours and when the injection of the vascular system has been accomplished they are to be returned to their respective places If the brain is also to be examined the scalp is divided from ear to ear over the vertex and drawn forward and backward with the periosteum and muscles, and the calvaria is sectioned horizontally without injuring the vessels of the dura mater In removing the brain the arteries should be divided sufficiently far above the base of the skull to permit of their being easily ligatured. On the examination of the brain being completed it should be placed in preservative solution The interior of each of the cavities opened having been carefully washed and dried a systematic search has to be made for all divided vessels, and such of them as have not already been ligatured must now be secured, the foramina of the base of the skull also must be tightly plugged from above with cotton wool moistened with a thick solution of gum acacia A large cannula is then to be introduced into the aorta and firmly secured, the injecting apparatus having been attached to it the injection of the vascular system may be proceeded with Although apparently all the principal vessels have been tied, yet when the injection solution is turned on it will be found to escape at numerous points where divided vessels have been overlooked, just as takes places in an amputation of a limb when the tourniquet is slackened, these must be secured by ligatures or compression forceps as rapidly as possible. In consequence of the loss of preservative solution which inevitably takes place, notwithstanding that the pressure with which it is injected has been reduced to the lowest possible point, considerably more will be required than in ordinary cases where the embalming is done in the first instance, the operation is also greatly prolonged and much patience has to be exercised in performing it. There is, however, no reason why it should not be successful if thoroughly and carefully carried out.

Stratford place, W

THE QUIESCENT OR LATENT PERIOD IN THE COURSE OF GRAVE ABDOMINAL INFLAMMATION[1]

BY A. H. TUBBY, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO WESTMINSTER HOSPITAL AND TO THE EVELINA HOSPITAL FOR SICK CHILDREN, ETC

IN cases of acute abdominal lesions where the diagnosis is in doubt the simplest thing to do is to perform an abdominal section, but as surgery is a science as well as an art all are agreed that no exploratory operation should be performed without justification. There is, however, a debateable ground—a period of repose or quiescence—where instinct or intuition tells that the patient is suffering from a grave abdominal lesion. Year by year, as these affections are more closely studied and as clinical and pathological data accumulate, the debateable ground becomes gradually narrowed, but every surgeon from time to time in the course of his experience meets with cases in which he has conscientious doubts as to whether he should operate or should withhold his hand Unfortunately, too, the effect of not sufficiently grasping the true state of affairs is more disastrous in this region than elsewhere and cases can be recalled in which, after an acute onset, the pain subsides, the vomiting ceases, the temperature falls to normal, and the patient expresses himself as being tolerably comfortable But subsequent experience shows that this change in the symptoms is by no means significant of real improvement Sometimes this period is a deceitful and treacherous calm and as likely as not marks the onset of grave complications which terminate fatally It is this interval of apparent remission in the course of the disease which I venture to term the quiescent or latent period—quiescent in so far as the disappearance of some of the symptoms is concerned and latent in that it precedes an aggravation of trouble, acute peritonitis, and a fatal issue

I was much struck by a case which I was called to see some years ago. It was that of a married lady, aged 30 years, who, with a history of somewhat ill-defined dyspepsia for some years, was suddenly seized with acute pain about the umbilicus on a certain Monday afternoon. The pulse quickened, the temperature rose to 100 4° F, and the abdomen rapidly became tympanitic. On the next day the symptoms remained much the same until towards evening when a marked improvement took place. I was asked, however to see her in consultation on the Wednesday I found her free from pain the pulse and temperature normal, the facial expression placid, and apparently there was no need for any surgical interference. She was however, kept in bed and carefully fed by rectal enemata as it was suspected that leakage might have taken place from a gastric ulcer On the Friday the symptoms returned suddenly and with great violence. I was called to see her in the evening and prepared to operate. She had been placed under the anæsthetic when suddenly she vomited and brought up a large quantity of blood and life was soon extinct. Unfortunately no post mortem examination could be obtained The period of calm in this case, which occurred from the Tuesday night to the Friday morning is an example of what I mean by the quiescent or latent period in acute abdominal affections. I do not myself doubt that there was some one symptom present, more or less marked, that escaped my attention which, had I known it, would have revealed the full significance of the first onset, and if I had been called to the case at this time I should have examined the blood for leucocytosis. It is probable that when the attack first came on an ulcer had eaten its way down to the peritoneum and a little leakage had occurred the aperture being plugged by inflammatory lymph, but the ulcerative process went on rapidly until a large vessel was eaten into. And looking backwards on the case there is no doubt that the patient ought to have been operated upon during the quiescent period.

---

[1] A paper read before the Medical Society of London on April [illegible]th, 1902.

It must be confessed, however, that it is extremely difficult to be always wise at the time and in contrast with this case I will allude to another gastric case. *About three years ago* I was asked by Dr. B. N. Dalton of South Norwood to see a case with a view to operation which he had diagnosed as perforated gastric ulcer, the onset having occurred about 18 hours previously. We operated, found the perforation, and applied an omental graft and the case did quite well. About eight months subsequently, in Dr. Dalton's absence on his holiday, I was sent for again to see this patient. She had had rather a fatiguing day in London and being hungry had eaten some ham sandwiches rather late at night. In the early morning she was seized with sudden pain and some vomiting and I saw her the same afternoon. When I arrived I found some tenderness over the upper part of the right rectus and rigidity of the muscle there but no tympanites and the liver dulness was normal. On the occasion of the previous attack the liver dulness had been lost. I therefore decided to postpone the question of operation and to watch matters carefully and, as events proved, that was the right course to be taken, for she has, so far as I know, never been troubled since with her stomach in any way.

But while the quiescent period was fairly well marked in *the first of the stomach cases which I have quoted*, yet there are many cases other than gastric in which it is better marked and I should be disposed to say that the quiescent or latent period is from time to time a prominent feature in the following group of cases:—1. Injury to the intestines with or without rupture. 2. Perforation of the intestines by ulceration. 3. Injury to, and bruising of, the peritoneal connexions of the viscera, with interference with their blood-supply. 4. Acute diseases of the genital organs, especially of the Fallopian tubes. 5. Acute appendicitis, either ulcerative, perforating, or gangrenous, and this disease undoubtedly affords by far the greater number of examples of apparent improvement. In order to give point to my remarks I should like to quote some cases from surgical literature.

1. *Traumatic rupture of the intestine.*—Dr. J. J. Buchanan[2] reports a case of a young man, aged 18 years, who was struck in the abdomen at 5 o'clock one morning by an iron implement. When seen five hours afterwards he was unable to say where he had been struck. *No ecchymosis*, or sign of contusion, or area of tenderness was present. His general condition was good and his pulse was of good volume, regular, and 88 to the minute. The temperature was 98° F. There was no abdominal distension or excessive rigidity of the muscles but the abdominal wall had not its normally soft condition. He had vomited after the accident and once after admission to the hospital. Dr. Buchanan, on examining him, noted that peristalsis was almost absent, and on this symptom, taken with the slight rigidity and the fact that he had vomited twice, abdominal section was decided upon and was performed at 11 A.M. (six hours after the accident). On opening the peritoneum thickened and congested bowel presented itself and sero-purulent fluid escaped. On further examining the intestine a rupture of the small intestine about a third of an inch in length was discovered with fæcal matter exuding. This was sewn up, the peritoneal *cavity was douched* with saline solution, a drainage-tube was put in, and the patient ultimately recovered. At the same time it must be admitted that there are many cases in which there is marked evidence of contusion of the abdominal wall with considerable collapse which recover entirely without operation.

2. *Perforating ulcer of the intestine.*—This condition affords excellent examples of this latent period. I quote a case described by Dr. A. B. Johnson,[3] in which a man, aged 27 years, was admitted to the Roosevelt Hospital with a history that four days before admission he was seized with colicky pains about the umbilicus but there was no vomiting. His pains were not severe and his bowels were moved daily and he remained at his work. At 1.30 A.M. on the day of his admission he was seized with severe abdominal pains followed by a chill. On admission the abdomen was not distended. It was markedly tender and was rigid throughout. Eight hours after admission the abdomen was opened and a good deal of cloudy, bile-stained fluid, with flakes of coagulated lymph, escaped. The vermiform appendix was examined but was found to be healthy, and ultimately upon the anterior surface of the descending portion of the duodenum a small perforation was found forming the floor of an ulcer. The perforation was closed and the patient recovered and six weeks afterwards he was in the best of health. In *this case the quiescent period, or at any rate the period in* which grave symptoms appeared to be absent, lasted for four days.

3. *Injury to, or bruising of, the peritoneal connexions of the viscera.*—Still more deceptive than the cases which I have quoted are those where there has been injury to the blood-supply of the intestine or bruising of the peritoneal connexions. As an example of this I may quote a case which occurred while I was a dresser. It was that of a middle-aged man who was knocked down in the street by an omnibus, the front wheel passing over him obliquely from the pubes to the left lumbar region. He was much collapsed when brought to the hospital but there were no distinct symptoms. After three or four days he recovered and it was thought that he might be discharged, but that experienced surgeon, the late Mr Davies-Colley, preferred to watch the case, and on the eleventh day after the injury the patient was suddenly seized with acute symptoms of peritonitis and he died in a few hours. On examination it was found that a considerable portion of the great omentum had sloughed.

A very remarkable case of traumatic rupture of the mesenteric arteries is reported in the *Annals of Surgery* for March of this year. A very heavy man, aged 53 years, slipped and fell and sustained a fracture of the bones of the leg, and some symptoms of shock were noticed. There was no pain in any other part of the body. On the following day the patient seemed weak but was easy and cheerful. His temperature was 99 5° F. and the pulse was 99. The urine was scanty but it contained no abnormal constituents. On the following day his condition had altered for the worse and it continued to do so during the next four or five days but no definite diagnosis could be made. There was some slight distension of the abdomen but careful percussion revealed no localised dulness or undue resonance. He was extremely pallid and breathed irregularly; his temperature was subnormal and his pulse was 160, and it was thought that he was dying from internal hæmorrhage. On the seventh day after the accident he died and on opening the abdomen a large quantity of blood was found which was due to the ruptured walls of several of the mesenteric arteries. The mesentery contained an enormous amount of fat and there can be no doubt that in the pull exerted upon this structure by the violent fall it and its vessels were lacerated. In this case the latent period may have been due to the slow hæmorrhage and absorption of the liquid portions of blood in the early stages of the case by the peritoneum.

4. *Acute diseases of the genital organs.*—The records of gynæcology furnish numerous examples of acute diseases of the genital organs, especially of ruptured Fallopian tubes from pyosalpinx and tubal pregnancy, where the serious nature of the disease has not been at once evident.

5. *Acute appendicitis.*—The latent period, or, as Mr. Charters Symonds[1] in his very able and instructive Hunterian Oration designated it, "the period of repose," is extremely well marked in cases of appendicitis. He mentions one case of a female, aged 20 years, who was seen 48 hours after an acute *onset and was considered so* well on arriving at the hospital that operation was postponed until the next morning when a foul abscess was evacuated, and he says that "in nearly all the acute cases a stage is reached soon after the onset marked by a cessation of all acute symptoms The patient passes, unaided by sedatives, into a condition of repose. This period, if wrongly interpreted, may lead to disaster. It is in its early stage a period of safety, one in which operation is successful." I may give two cases from my own experience. One was that of a young woman, aged 18 years, who after a day in town, where she had partaken of a couple of ices and later in the day of a raw apple, was seized early on the following morning with acute pain and vomiting and sickness. This subsided after 24 hours and her condition improved during the next 48 hours so that she was able to get up and to go about almost as usual. On the fourth day intense pain in the abdomen set in, the vomiting returned, and she was prostrate. The parents were urged by the medical attendant to have surgical assistance but this was refused until the fifth day of the illness and when I saw her the

[3] Ibid., vol. xxx., p. 634.

Brit. Med. Jour., 1899, vol. i., p. 520.

condition was that of acute septic poisoning. The temperature was 100° F. and the pulse was 124. The abdomen was distended, with no sign of tumour or dulness, and, in fact, she presented a picture of virulent peritonitis. As a remote hope an operation was undertaken and a long, much distended appendix was found but her condition became so bad that it was not possible to remove it. The abdomen was washed out with saline solution and the appendix was packed round with strips of iodoform gauze. For 12 hours she showed a marked improvement but then aggravated symptoms set in and she succumbed 24 hours after the operation. The other case was that of a young man, aged 18 years, who after a bicycle ride on a certain Sunday was seized with acute abdominal pain while away from home. After 24 hours, however, he felt well enough to return home and he appeared to be doing well and remained in fair condition until 2 P.M. on the following Tuesday, when the pain and vomiting returned and his general condition was that of collapse. I saw him at 4 A.M. on the Wednesday and found his pulse uncountable, his temperature 101°, his abdomen distended, but with tenderness and an ill-defined mass in the right iliac fossa. On opening the abdomen I evacuated some foul pus from the right iliac fossa. After the operation his pulse improved somewhat and he expressed himself as being free from pain but he did not survive the operation for more than 24 hours.

These are instructive instances of the subtlety of these cases but the most striking cases that I have ever read of are those quoted by Sir Frederick Treves in his work on Perityphlitis at p. 27. He says that he has seen two cases of septic peritonitis, due to trouble in the appendix, run their entire course with a flaccid abdomen and with scarcely any tenderness. Both patients were men over 50 years of age. No morphia had been administered and in both cases death took place from toxæmia, within seven days. One man spent some hours in applying massage to his own abdomen and the other drew frequent attention to the absence of tenderness by slapping the abdominal wall. In all these instances, although the usual train of symptoms of virulent mischief was not present, yet there was some one sign or other which subsequent investigation showed to afford sufficient grounds for surgical interference without delay. It may have been either that the remissions were never quite complete or that the usual course of things differed by the persistence of some symptom. Thus muscular rigidity—slight it may have been—may have persisted, peristalsis may have been absent, some tenderness may have been elicited on careful palpation, the pulse may have been out of proportion to the temperature, or the general appearance of the patient—deceptive though it may be to the casual observer—may have suggested to the experienced eye that all was not well. Again, it is extremely difficult to gauge the value of symptoms or signs slightly marked when the deceptive remission has been brought about either by drugs or by the application of ice-bags. As to what is the explanation of this quiescent period it is difficult to say, but in some cases where tenderness has been absent—as, for example, in cases of very acute appendicitis—it has been found that the appendix is gangrenous and that its nerves are therefore insensitive. And so it may be that in cases of acute general peritonitis the sensory nerves of the peritoneum are paralysed from the first. Doubtless there are other causes at work but it is not within the scope of this paper to discuss them.

A careful compilation of abdominal cases and the recording of clinical signs fortunately enable us to fix upon certain symptoms—even in obscure cases—as of great moment.

1. The most important information is gathered from repeated records of the *pulse and temperature.* These may rise together in due proportion: or there may be a slightly elevated temperature with an entirely disproportionate pulse-rate; or the temperature may be subnormal when taken on the surface, while the pulse may be greatly accelerated. It is this last condition that is more often met with during the latent period in very grave cases, and taken with a history of the onset of the attack it affords justifiable grounds for immediate operation. In all abdominal cases the pulse and temperature should be frequently taken, at least every three hours, although the disease appears to be quieting down. Remembering what has been said as to the probability of a successful issue to an operation if it be undertaken in the early part of the latent period, this inverse relationship of temperature and pulse should be observed at the earliest possible time. If the altered relationship has been established for a day or two, then the prospects of operation are extremely unfavourable, because by that time the patient has probably become saturated with septic products. Again, it may happen—as, for example, in the course of an attack of acute appendicitis—that after an initial rise of temperature and pulse there is a fall in both, succeeded after a few days by a rise. This indicates the presence of a considerable amount of pus, and unless the abscess be evacuated there is a grave danger of it bursting into the peritoneal cavity.

2. In the case of the perforating duodenal ulcer which I have quoted there was no vomiting or severe pain and the patient was able to remain at his work, *rigidity*, with some tenderness, being the only definite symptom; but on opening the abdomen it was found that there was acute peritonitis present, and perhaps of all the physical signs a transient or a persistent rigidity and the absence of other symptoms are the most valuable and they become convincing when signs of intestinal peristalsis are absent.

3. It is difficult to speak of *distension* as a symptom taken by itself, for it is often absent in the early stages, even in so serious an affection as a perforating gastric ulcer; but in the late stages of abdominal diseases the fatal significance of it is only too well known. But distension which persists for longer than for from 24 to 36 hours and is unrelieved by treatment such as a turpentine enema is of grave moment.

4. As a rule, *vomiting* is quite absent during the quiescent period. It is true that at the beginning of the illness there may have been vomiting but at the "period of repose" the vomiting has subsided, it may be because the stomach has been emptied of its contents by the initial sickness or because the vomiting has been kept in check by the administration of sedatives. But if the vomiting recurs in spite of careful feeding, careful nursing, and more especially if it persists after the administration of sedatives, the symptom is not one to be under estimated.

5 A great deal of careful work has been done on the subject of *leucocytosis* of late, and not only on leucocytosis but on the condition of the blood generally in abdominal affections Dr. Da Costa[5] states as the result of his researches that in an appendicular abscess the number of leucocytes per cubic millimetre present in the blood may be from 15,000 to 20,000, the normal number of leucocytes being from 5000 to 7000 per cubic millimetre and rising to 12,000 at the height of digestion after a good meal. He further adds that if the pus focus be walled off and no absorption of toxic material takes place, then there may be no rise in the number of leucocytes, but otherwise in purulent appendicitis their number may vary from 14,000 to 58,500, and he found the average in purulent cases to be 17,450. In perforative appendicitis there is a very abrupt rise of leucocytes and counts of over 20,000 indicate either pus, gangrene, or peritonitis. If the number be under that the deduction is uncertain, for in 35 per cent. of non-purulent cases there is merely a small increase in leucocytosis. As showing, however, that even this sign is not to be absolutely relied upon, Dr. Da Costa states that in some septic cases arising from appendicular trouble there is an absence of leucocytosis, and if this occurs it is a symptom of very grave importance. From a diagnostic point of view it should be remembered that leucocytosis is absent in typhoid fever but is almost invariably present in ovarian abscess, pyosalpinx, perinephritic and nephritic abscesses, and in suppuration generally. Dr. J. T. Finney,[6] writing on perforating ulcer of the stomach, quotes Dr Cabot who states that leucocytosis is never seen in the course of gastric ulcer except after severe hæmorrhage and at the height of digestion. The presence of leucocytosis when the influence of bleeding and digestion is excluded is "practically unknown in uncomplicated gastric ulcer" When, therefore, grave symptoms occur in a young woman with a history of previous digestive disturbance, together with a sudden development of marked leucocytosis, the indications for immediate surgical interference are imperative. A most instructive article on the leucocyte count in surgery is given by Dr. Theodore Dunham.[7] He gives many interesting details, some of which are as follows. There is considerable leucocytosis after the administration of ether. In acute cervical adenitis in an infant, aged seven and a half months, the leucocyte count was 9800 and with a mastoid abscess 24,800, and with a gangrenous appendix 17,000, rising next day

[6] Annals of Surgery, vol. xxxiii., p. 6.

[7] Ibid., vol. xxxi., p. 669.

to 19,000. In another case the appendix was operated upon and the day after operation the count was 11,700, and on the following days it was 14,500, 16,900, and 22,100. Meanwhile the dressings, the temperature, the pulse, and the respirations gave no distinct indication of anything wrong, but at the dressing after the last-named count a large quantity of pus had found its way into the wound.

Mr. J. H. Hebb has very kindly made some observations for me at the Westminster Hospital upon leucocyte counts in various conditions, suppurative and non-suppurative. A male patient was admitted suffering from appendicitis with a temperature of 99° F. The leucocyte count was 11,562 (finely granular 54, coarsely granular 17, hyaline 9, and lymphocytes 20 per cent). This case subsided without suppuration and did well. A female patient was admitted on Feb. 15th suffering from suppurative pelvic cellulitis. The leucocyte count was 22,500. On March 1st, when the suppuration was subsiding, the count was 15,625. A female patient suffered from pelvic cellulitis and a very extensive abscess on the outer side of the thigh, which had made its way from the pelvis through the great sciatic notch. The temperature was 98° F. On admission leucocytosis was 13,128 (finely granular 43, coarsely granular 4, hyaline 10, and lymphocytes 43, per cent.). On March 3rd, when the suppuration was less, the count was 11,560 (finely granular 64, coarsely granular 5, hyaline 6, and lymphocytes 25, per cent.). So far, then, it may be said that in the leucocyte count frequently made in the course of the illness there was a very valuable indication that grave mischief was going on even when the other symptoms were quiescent or latent and this method of clinical investigation promises to be one of the utmost value.

6. In regard to *chest complications*, in a patient who began his illness with symptoms referable to the abdomen but who remains ill although the symptoms in that region have apparently subsided careful examination of the chest and the detection of either a pleuritic rub or the presence of fluid in either of the pleural cavities may serve as an indication that mischief is still going on in the abdominal cavity and that exploratory operation is called for. In Dr. J. Mitchell Bruce's excellent Hunterian lecture, delivered in November of last year, the subject is fully dealt with and he quotes an instructive case of pleurisy and perigastric abscess which was operated upon by Mr. Rickman J. Godlee who found serous fluid in the left chest and a perigastric abscess below the diaphragm. A somewhat similar condition is met with in cases of appendicular trouble where the abscess has tracked up into the renal regions and associated with it fluid has been found in the chest. It may be that the trouble has almost, if not quite, subsided in the region of the appendix and what has to be dealt with is a continuous lymphatic infection in the post-abdominal connective tissue and extending through the lymphatics to the diaphragm and so causing chest symptoms. The detection of fluid in the chest, especially on the right side, may lead on exploratory operation to the further detection of a collection of pus, either sub-diaphragmatic or situated deeply in the flank.

The remarks which I have made on this difficult clinical subject are, I fear, fragmentary and imperfect, but if they lead to a more thorough investigation of that all-important period—latent, quiescent, or reposeful—I feel that what has been written may be of some service.

Weymouth-street, W.

SOME OF THE SURGICAL ASPECTS OF GLYCOSURIA AND DIABETES.[1]

By LLEWELLYN C. P. PHILLIPS, F.R.C.S. ENG.,
RESIDENT SURGICAL OFFICER, KASR EL-AINI HOSPITAL, CAIRO, EGYPT;
LATE DEMONSTRATOR OF ANATOMY, ST. BARTHOLOMEW'S HOSPITAL.

ON referring to old surgical case-books it is not unusual to find a clinical history ending with the statement that no operation was performed as the patient was suffering from glycosuria. Surgical text-books still advise that when diabetes is present no active surgical measures should be undertaken unless urgently required. Since, however, the word "urgency" is capable of widely diverse interpretations it is advisable to study the results that have been obtained after operations upon diabetics and the causes of failure in order to define the limits of surgical interference. In the pre-antiseptic era most of those diabetics who came under the hands of a surgeon were suffering from gangrene or carbuncle and therefore in many cases already affected with some form of septic poisoning. It is not, therefore, surprising that the mortality was high and thence arose the dictum still found in most text-books.

CLASSIFICATION OF THE CAUSES OF GLYCOSURIA.

In many instances it is very difficult to distinguish between temporary or non-diabetic glycosuria and true diabetes; this is especially so in the presence of surgical complications, and were the presence of sugar to be taken as due to the existence of diabetes in all cases then doubtless many patients would die unrelieved. Various classifications have been drawn up, the best of which, from a surgical standpoint, is that by Smith and Durham, though in some respects deficient. The following is therefore proposed: (1) those cases in which glycosuria is caused by the surgical lesion; (2) those cases in which it causes the surgical lesion; (3) those cases in which the two are independent and do not influence each other; and (4) those cases in which glycosuria exerts a baneful influence upon the other disease or injury. Glycosuria may be merely temporary, apart from surgical diseases or injuries, as after certain drugs, as opium or chloroform (the toxic form), or it may be of alimentary origin. A diagnosis is often impossible, transitory glycosuria passing imperceptibly into true diabetes. A good instance of the toxic form is recorded by Marmaduke Sheild of a man who had taken morphia for years and sustaining a fracture of his patella underwent the operation of wiring. Sugar (not glycuronic acid) was subsequently discovered which disappeared gradually on the withdrawal of the morphia. Convalescence was uninterrupted.

CLASS 1.

Glycosuria has been noticed as a complication of a great variety of surgical ailments and injuries, the causes falling into two main groups—injury and sepsis; other less frequent causes also occur. Redard classified them into the following groups: (1) injury of the central nervous system; (2) other injuries, such as fractures and operations; (3) inflammation; (4) cellulitis, lymphangitis, and erysipelas; (5) carbuncle; (6) gangrene; and (7) septicæmia. In almost all his cases the amount of sugar was small and usually quite transitory, the amount varying from 0·1 to 2·29 per cent. and generally also accompanied by albuminuria and slight polyuria. Smith and Durham add to these certain cases of ulcerated new growths and consider that the sugar is secondary to the sepsis present. They quote one of Redard's cases as bearing out this hypothesis, in which 0·4 per cent. sugar was present the first day, 0·18 per cent the second day, but none the third day (epithelioma of the tongue). More recently many cases of intra-abdominal or intra-pelvic disease have been published in which glycosuria, apparently secondary, existed; but its duration was months and they closely simulated diabetes in other respects (thirst, polyuria, &c.). After operation, aided in some instances by general treatment, the sugar and the other symptoms permanently vanished. These cases differ extremely from those recorded by Redard and others and require close attention. They may be divided into two classes: (1) septic cases, and (2) non-septic cases.

1. *Appendicitis* (Table I.).—Leidy reports three cases and Cohen one of appendicitis, in two of which suppuration was present, which were complicated by glycosuria. In Leidy's first case 2·5 per cent. of sugar was found, expectant treatment was adopted, and recovery resulted; six months later and four years later sugar was entirely absent. In Cohen's case it lasted three months, disappearing as an abscess healed.

Pyosalpinx.—Imlach records a case in which polyuria, thirst, and constipation were present a month before the patient came under observation, the resemblance to diabetes being therefore great. Under diet the amount of urine fell to from five to six pints per diem; during the next month the sugar dropped from 2500 grains per diem to 1200 grains. Within a week of the removal of a pyosalpinx sugar permanently disappeared.

2. *Strangulated hernia.*—Neugebauer has reported two cases accompanied by glycosuria. Both were operated upon, the first without an anæsthetic on account of supposed diabetes; both recovered, the sugar disappearing the next day. In the second case 90 centimetres of small intestine were resected. After his first case he performed a species of

TABLE I.—CASES OF APPENDICITIS ASSOCIATED WITH GLYCOSURIA

No	Reference.	Sex and age	History.	Condition whilst under observation	Urine.	Treatment	Result	After history
1	Leidy	Female 29 years	At the age of 23 years the patient suffered from obstruction of the bowels and had had many attacks of pain in the right iliac fossa since.	A lump and a sinus leading to a fæcal concretion; right iliac fossa; the concretion discharged on the third day after admission	Specific gravity, 1032; alkaline; 2·6 per cent. of sugar no albumin	Expectant	Gradual recovery and a decrease in the amount of sugar	Six months later no sugar; four years later no sugar
2	„	Female 46 years	Pain in the right iliac fossa; sickness; constipation	Temperature, 103·4° F.; pulse, 110 A swelling in the right iliac fossa.	Specific gravity 1029; much sugar; a trace of albumin The amount of sugar varied whilst in hospital	„	Not stated presumably recovered	
3	„	Male; 25 years	Many previous attacks. The present attack started six months before and gradually subsided; a relapse later		Specific gravity at first 1032; sugar a trace of albumin; the sugar disappeared during convalescence and reappeared periodically	„	Recovery	During the last four weeks in hospital sugar was only discovered once
4	Cohen.	Male	Appendicitis first started in February with glycosuria but no polyuria or polydipsia An abscess formed which was opened on April 4th Much foul pus was evacuated The patient at the time was much emaciated Two days later there was still much glycosuria.		Sugar was present in February March and part of April	Expectant at first then the abscess was opened	„	In five weeks the patient was quite well. The glycosuria had disappeared

experiments and found that if all the intestine was ligatured or the upper part of the jejunum glycosuria resulted He attributes the rareness of its occurrence in strangulated hernia to the infrequency of strangulation of the upper part of the jejunum. In his cases the hernia was very large and contained almost the whole of the small intestine. (Glycosuria complicating strangulation may be commoner than is supposed but may be overlooked through neglecting to examine the urine.)

Ovarian tumours.—Croom has published the clinical history of a patient who was affected with a large colloidal ovarian tumour Her urine contained a trace of albumin and "much" sugar, its specific gravity was 1047 Diet and morphia being of no avail in reducing the sugar the tumour was removed. In two months the patient was quite well, having no trace of sugar in her urine. Diet was, however, still maintained. The tumour weighed 56½ pounds. Beyen has recorded a similar case in which 7 per cent of sugar was excreted in the urine, with all the symptoms of diabetes. A month after the removal of the tumour only 4 per cent sugar was present and in six months it had permanently disappeared under treatment. The tumour weighed 22 pounds and was also colloidal.

These cases are of the greatest importance, being on the borderland of diabetes The probable cause of the glycosuria in the last two cases was the increase in the intra abdominal pressure, the tumours being of great size. General treatment was adopted in addition to the surgical measures. The presence of sugar in no way interfered with convalescence It must be concluded, therefore, that in such cases, even though the *symptoms* of diabetes be present, an operation is not contra indicated.

Glycosuria complicating spreading traumatic gangrene (personally observed).—A printer aged 48 years, was admitted in July 1900 to St. Bartholomew's Hospital under the care of Mr H. T Butlin suffering from a lacerated wound of the left arm and forearm the result of injury in a printing machine. The skin had been torn up and the soft parts were much bruised. No sugar was present in his urine and there was no history of diabetes. The next day the arm was cold and slightly emphysematous. Sugar was now present in his urine. The discolouration of his skin spread and the temperature rose to 103·8 F in the evening The next day his arm was removed at the shoulder joint by a posterior quadrilateral flap; there was much hæmorrhage (? high division of the artery) Gas and ether were administered and the wound was lightly closed The day after the operation the temperature came down and 2·5 per cent. sugar was present. The amount of sugar varied, being 3·3 per cent. a week after the operation The wound, save for a small slough, gradually healed and the sugar permanently vanished. He was seen again in December but no sugar was present. There was much difficulty in the estimation of the sugar as the cuprous oxide would not precipitate properly No special diet was adopted and no special drug treatment. A gas producing anaerobic bacillus was cultivated but not identified.

CLASS 2.

It is doubtful whether diabetes can directly cause any lesion requiring surgical treatment except balano-posthitis and possibly cataract. So-called diabetic gangrene is rather gangrene occurring in a diabetic subject, the influence of diabetes being indirect through arterio-sclerosis or nerve degeneration, the result of the constitutional affection. Carbuncle is to be regarded in the same light. Such patients respond badly to injuries, whether surgical or accidental. Balano-posthitis is, however, due to the irritation of the sugar-containing urine. Smith and Durham have collected from French authors seven cases in which circumcision was performed, with six recoveries, one after extensive sloughing and erysipelas The fatal case was due to wide spreading sloughing and gangrene of the integuments the result of the operation. The best results were obtained by Francon who practised the most rigid antisepsis then known. As a precautionary measure Lauder Brunton has advised careful sponging of the prepuce and glans after each act of micturition in order to remove all trace of urine As regards cataract Legendre has collected 102 operations with 99 successes (Laisney's cases)

CLASS 3.

This is, from the surgical standpoint, the most important group of cases, as it contains most new growths, fractures, and other injuries occurring in diabetics The existence of diabetes may at the time be unknown, as the disease may be intermittent The patients may appear perfectly healthy, but they are more often stout and otherwise unfavourable subjects for operation (*diabète gras*) For convenience of reference the cases will be arranged regionally

Operations on the Face and Mouth.

Two parotid tumours have been unsuccessfully excised In the case recorded by Verneuil in 1878 after a tedious operation erysipelas set in on the fourth day and death occurred on the eighth day as the result of secondary hæmorrhage from the external carotid. The operation was not performed until general treatment had caused the sugar to disappear It reappeared after the operation. In the other instance the operation was quite simple but the patient died in coma on the third day Diabetes was not discovered beforehand. Redard successfully removed a myeloid epulis by the thermo-cautery without an anæsthetic. Preliminary

TABLE II.—OPERATIONS ON THE FACE, MOUTH, &C.

No.	Sex and age.	Reference.	Disease.	Operation.	Result.	General treatment.	Remarks.
1	Male, 45 years.	Verneuil (Bulletin de la Société de Chirurgie, 1878).	Parotid tumour.	Excised. Serious *operation.*	On the fourth *day erysipelas.* On the eighth day hæmorrhage from the carotid. Death.	Adopted until the sugar had disappeared.	Diabetes two years 3 per cent. of sugar. The sugar reappeared after the operation.
2	*Male*, 62 years.	Polaillon.	"	Excised. Easy operation.	Coma on the third day. Death.	—	Diabetes unknown before the *operation. Chloroform* was the anæsthetic. Sugar was *found on the appearance of* coma.
3	Male; 68 years.	Tuffier.	Epithelioma *of the floor of* the mouth; adherent to the mandible, ulcerated, had been *cauter*ised several times previously.	Removed.	Left lobar pneumonia on the fifth day Death on the seventh day.	Adopted until the sugar had disappeared.	0·2 to 0·3 per cent of sugar before the operation, traces after. Smith and Durham throw doubt on the nature of the glycosuria.
4	Male, 47 years	*Redard.*	Myeloid epulis of the lower jaw, rapid growth.	*Removed* by thermo-cautery.	Recovery.	Adopted as a preliminary. Diabetes for two years 3·77 per cent. of sugar.	Before the operation the total amount of sugar per diem *was from 13 to 29 grammes* It rose to 73 grammes on the sixth day after the operation and then fell.
5	Male. 62 years	Verneuil (Bulletin de la Societe de Chirurgie, 1884)	Epithelioma of the palate.	Removed by thermo-cautery *after incising the* cheek.	Hæmorrhage two hours later. *Next day* pneumonia and coma. Death.	—	Diabetic; alcoholic; 7·6 per cent. of sugar.
6	Male, 50 years.	Verneuil.	Epithelioma of the soft palate *and* the tonsil.	Cauterised with chromic acid.	Recovery.	Treatment did not diminish the sugar.	Diabetes seven years. 4·6 per cent. of sugar, urine, 2·75 litres. No recurrence Death two months later
7	Male, 65 years	Richelot	Epithelioma *of the inner* surface *of the* cheek.	Removed together with an enlarged gland.	Slight suppura*tion in the cervical* wound. Recovery.	Adopted. Reduced the percentage of sugar *from* 4 *to* 3·3 and the urine from three to 1·5 litres.	Old diabetes Carbuncle seven years previously.
8	Female, 64 years.	Maunoury.	Epithelioma *of the mouth.*	Removed by thermo cautery *after slitting the cheek.*	Gangrene of the skin (emphysematous) spread *all over the head.* Death.	—	Three years' history of diabetes *elicited on the* occurrence of sepsis. 8 per cent. *of* sugar
9	Male, 64 years.	Tuffier.	Epithelioma of the tongue and the pillar of the fauces.	Removed by thermo-cautery.	Recovery.	Adopted for 15 days. The sugar vanished	Intermittent diabetes two years 0·4 per cent of sugar. The sugar reappeared after the operation.
10	Male, 52 years.	"	Epithelioma of the tongue.	"	"	Adopted until the sugar had vanished.	Intermittent diabetes four years. Sugar reappeared on the day after the operation 0·8 per cent on discharge.
11	Male; 50 years	Verneuil (Bulletin de l'Académie de Medecine, *1881).*	Epithelioma of the tip of the tongue.	"	Secondary hæmorrhage on the sixth day. *Bronchitis.* Recovery.	Adopted for about 10 days beforehand.	Sugar fell to 0. Total sugar before 5·4 grammes.
12	Male, 32 years	Tuffier.	Epithelioma of the border *of the tongue.*	"	Slight secondary hæmorrhage Recovery	Adopted until the sugar had disappeared (a few days).	0·4 per cent of sugar. Smith and Durham consider this to be glycosuria consequent on ulceration. Such was *probably* the case.
13	Male; 72 years.	Fischer.	Epithelioma of the lip.	Removed.	Recovery.	Adopted for from four to five months before operation	Sugar diminished from 3·45 per cent. to 0.
14	Male.	Reynier.	Epithelioma of the *lower* lip.	"	The wound broke down *partially.* It healed in one *month.* Recovery.	No mention.	The amount of sugar was at first 60 grammes. At the *time of the operation it was* from 10 to 15 grammes.
15	"		Epithelioma of the lip.	"	Recovery.	—	Atheroma, alcohol, syphilis,
16	Male, 52 years.	"	—	Excision of the eye.	"	Adopted. Caused the sugar to disappear.	—
17	Male; 32 years	"	Sebaceous cyst on the neck *of the* size of an orange.	Removed.	"	—	"Diabetique gras."

TABLE III.—OPERATIONS ON THE BREAST.

No.	Sex and age.	Reference.	Disease.	Operation.	Result.	General treatment.	Remarks.
1	Male; 50 years.	Fischer, 1878.	Scirrhus (ulcerated).	Amputation. Glands removed.	Cellulitis on the second day. Gangrene of skin of back. Recovery.	Adopted on the discovery of sugar. Carbolic acid internally.	2·2 per cent. of sugar.
2 a	Female; 56 years.	Tuffier.	Scirrhus of the right breast.	Amputation.	Recovery.	Adopted for some months previously.	
2 b			Recurrence in the glands nine months after.	Glands excised.	,,		Glycosuria three years. On the fifteenth day 0·3 per cent.
3	Female; 61 years.	Rosenberger, 1882.	Scirrhus of two years' history.	Amputation.	Most of the wound healed by first intention, but on the fourteenth day sepsis from the drainage wound occurred. Death.	Had been adopted some years before.	Diabetes six years.
4	Female.	Berger.	Encephaloid of the right breast.	Amputation. The glands were also removed. No attempt was made to close completely the wound.	Recovery.	Adopted until the sugar had disappeared.	Severe diabetes 10 years. 4 to 5 per cent. of sugar. Died. Two ovarian growths four months later.
5	Female, 50 years.	Noble.	Scirrhus.	Amputation. The glands and the pectoral fascia were removed.	Slight axillary suppuration. Recovery.	Diabetes was not discovered until after the operation.	
6	Female, 65 years.	Willett (St. Bartholomew's Hospital Surgical Register, vol. i., 1898).	Scirrhus (left).	Amputation. The glands were also removed.	Healed mainly by first intention. A small abscess was found on the tenth day. Recovery.	Presumably dieted as she was transferred from a medical ward.	Diabetes seven years. 4·5 per cent. to 2·25 per cent. of sugar. Total per diem 45·5 grammes to 16·23 grammes.
7	Female.	Willett (private case).	Scirrhus.	Amputation.	Recovery.	Diabetes was discovered after the operation. very stout patient.	
8	,,	Lilienthal.	,,	,,	,,	—	Sugar persisted.
9* a	Female; 61 years.	Fisk, August, 1895.	Scirrhus (ulcerated), right breast.	Amputation after Halsted's (?) method.	—	Not adopted.	Diabetes. 2·5 per cent. of sugar. Ether.
9* b.	—	—	—	Thiersch's skin-grafting 14 days later.	—	—	—
9* c.	—	March, 1898.	Small recurrence.	Removed.	—	—	Cocaine.
9* d.	—	November, 1898.	Fresh ulcerated recurrence.	Excised with portion of a rib.	Granulated up.	—	2·2 per cent. of sugar. Still alive in August, 1899.
10	Female; 64 years.	Tuffier (No. 11), 1881.	Carcinoma of the right breast. 18 months.	Amputation.	Erysipelas. Death on the fifth day.	—	No sugar before the operation. Urea, 1·8 per cent. After the occurrence of erysipelas "much sugar." Smith and Durham consider the glycosuria to have been caused by the occurrence of erysipelas.
11 a.	Female; 64 years.	Le Conte (details by letter), 1899.	Recurrent scirrhus. The breast had been removed three years before with the glands.	Free excision of recurrence. The second and third ribs were involved but were not removed. A large operation, skin-flaps being necessary.	Recovery.	—	Ether. From 4 per cent. to 11·5 per cent. of sugar present.
11 b.	—	—	Six months later another recurrence.	Excised.	,,	—	Ether. No sugar.
12	Female.	Reynier.	Carcinoma of the mamma.	Amputation.	,,	Adopted. Total sugar per diem reduced from 35 grammes to 11 grammes. As the result of the operation the sugar rose again to 28 grammes. Atheromatous vessels.	
13	—	,,	—	,,	,,	Atheromatous vessels.	
14	Female.	Reynier (with Dr. Marieux)	—	,,	,,	Diabète gras.	
15	Female; 61 years.	Butlin (St. Bartholomew's Hospital Female Surgical Register, vol iv., 1900, p. 432)	Scirrhus (in small spheroidal cells).	Amputation of the breast with free removal of the skin and some of the pectoralis major. March 2nd, 1900.	,,	Drained for two days. Convalescence was uneventful. Tumour in the upper and inner quadrant of the breast. The skin was adherent but not ulcerated. Diabetes was first detected in June, 1899. Some sugar in the urine on the day of admission to hospital; none on the day of operation, or after. A stout subject. No special diet, or medicinal treatment.	

---

* This patient underwent four operations successfully and was alive four years later, although the primary growth was ulcerated to the extent of two inches by one and a half inches.

TABLE IV.—OPERATIONS ON THE FEMALE GENERATIVE ORGANS.

No.	Age.	Reference.	Disease.	Operation.	Result.	General treatment.	Remarks.
1	33 years.	Matthews Duncan (Sir John Williams's case).	Rupture of the perineum into the rectum.	Perineorrhaphy eight months after the rupture. (Primary operation having failed.)	Recovery.	Adopted.	Diabetic symptoms present on and off for 13 years during pregnancies.
2	—	Baldy. (Unpublished case.) By letter. 1900	Prolapsus uteri. Lacerated cervix.	Cervix repaired. Curetting. Plastic operation on the anterior and posterior vaginal walls.	,,	Strict preliminary dieting, &c.	2·5 per cent. of sugar. A trace on discharge.
3	—	,,	Procidentia, &c.	Amputation of the cervix. Plastic operation on the anterior and posterior vaginal walls. Ventrofixation.	,,	,,	About 2·5 per cent. Discharged in three weeks.
4	—	Baldy (*vide* discussion on Noble's paper).	Procidentia.	Plastic operation.	,,	—	"Much sugar."
5	—	,,	,,	,,	,,	—	,,
6	—	,,	Complete tear of the sphincter ani.	Perineorrhaphy.	,,	Sugar and opium reduced whilst in hospital.	Diabetic and opium-eater for years. Six years later still diabetic.
7	48 years.	Kleinwächter.	Fungous endometritis. Lacerated cervix with erosion. Warts on the vulva.	Curetting. Repair of the cervix. Removal of warts.	Wound healed rather slowly; recovery.	—	Thirst; polyuria. Sugar disappeared under dieting. Two years later well, probably diabetic.
8	—	Landau.	Torsion of an ovarian cyst.	Ovariotomy.	Recovery.	—	Emergency operation. Diabetes *only discovered after* the operation.
9	—	,,	Ovarian cyst.	,,	,,	Dieting until an irreducible minimum of sugar was reached.	Rigid antisepsis. One and a half years later still a small sinus in the wound.
10	—	,,	,,	,,	,,	,,	Rigid antisepsis.
11	?	Loeb (Schröder's case).	Double dermoid ovary.	,,	Death.	—	A sister also diabetic. A very difficult and tedious operation on account of numerous adhesions.
12	63 years.	Reynier.	Malignant disease of the ovary.	,,	Death on the fortieth day.	—	The wound apparently progressed favourably, but on the fourteenth day it gaped and the intestines protruded. It was re-sutured but did not unite. Death resulted on the fortieth day.
13	60 years.	Kreutzmann.	Epithelioma of the cervix.	Vaginal hysterectomy.	Recovery.	Diet reduced. Sugar before the operation.	Chloroform. Easy and rapid operation. The diet was continued after, sugar only reappearing in small quantities from time to time.
14	41 years.	Landau.	Carcinoma uteri.	Vaginal hysterectomy (22 minutes).	Coma on the second day. Death.	—	Diabetes for one year. Sugar entirely absent before the operation. No symptoms present. Marked euphoria. Strict diet had been employed earlier in the year.
15	63 years.	Landau (unpublished). Letter, 1901.	Carcinoma cervicis uteri.	Vaginal hysterectomy, Dec. 8th, 1900.	Recovery.	Carbohydrates withheld.	3 per cent. of sugar. Chloroform. Discharged on Dec. 31st, 1900. The *diet did* not diminish the sugar.
16	50 years.	Noble.	Procidentia uteri. Small ovarian tumour.	Vaginal hysterectomy and anterior colporrhaphy.	Death on the sixth day. Coma.	Diet, codeine, and strychnine.	Glycosuria for three years. No symptoms. Specific gravity of urine, 1026; sugar, 2·5 per cent. Diet, &c., reduced *it to* 1·75 *per cent.*
17	38 years.	Gottschalk (Berlin). Details by letter, 1901.	Fibroids. Uterus.	Abdominal hysterectomy, 1893.	Recovery.	Carlsbad regimen.	Uterus reached 14 centimetres above the umbilicus. Much hæmorrhage from the uterus. 1 per cent. of sugar in 1893; 0·6 per cent. in 1901. Chloroform.
18	47 years.	Landau (unpublished). Letter, 1901.	Intramural myoma of the size of a man's head.	Abdominal enucleation, Feb. 2nd, 1901.	,,	Diet.	Slight suppuration in the wound. Sugar, 0·5 per cent.; unaffected by diet. Discharged March 21st, 1901. Chloroform.
19	53 years.	,,	Multiple fibroids. Umbilical hernia.	Abdominal hysterectomy (the right ovary left behind). Radical cure of the hernia.	,,	,,	Wound healed by first intention. Diet removed the sugar (0·5 per cent.). Operation on Feb. 27th, 1901; discharged on March 21st, 1901. Chloroform.

TABLE IV.—OPERATIONS ON THE FEMALE GENERATIVE ORGANS—(*Continued*).

No.	Age	Reference.	Disease.	Operation.	Result.	General treatment.	Remarks.
20	—	Reynier.	—	Abdominal and vaginal hysterectomy.	Recovery.	—	The wound gaped on the thirteenth day and was re-sutured, recovery eventually resulting.
21	"Young."	Noble (Norris's case).	—	Curetting.	Coma. Death on the third day.	—	—
22 a	54 years.	Champneys (unpublished). St. Bartholomew's Hospital Register, vol. vi., 1896	Epithelioma vulvæ.	Excised.	Recovery.	—	After the second operation (on the glands) the patient removed her dressings and slight suppuration resulted. Specific gravity of urine, 1035; sugar, 4·5 per cent.
22 b	—	—	Glands enlarged.	"	"		
23	55 years.	Kleinwächter Zeitschrift für Geburtshülfe and Gynäkologie, Band xliv.	Myoma of the uterus. Umbilical hernia.	Removal of the tumour (polypoid) p. v. Curetting	"	Adopted beforehand (sent to Karlsbad).	Sugar from 1·4 to 3·2 per cent. Absent at the time of the operation. Recurred afterwards from injudicious food. Diabetes.
24	43 years.	Giles.	"	Hysterectomy. Radical cure of the hernia.	"	—	5 per cent. of sugar but no symptoms of diabetes. Sugar persisted for one week after the operation. Discharged cured in three weeks.

Cases in which Diabetic Symptoms which were previously present disappeared after Operation.

No.	Age	Reference.	Disease.	Operation.	Result.	General treatment.	Remarks.
25	53 years.	Croom.	Colloidal tumour of the ovary. Weight, 68½ pounds.	Ovariotomy.	Recovery.	Before the operation general treatment and morphia had no effect. After the operation, under general treatment, the sugar gradually vanished.	Specific gravity of the urine, 1047; much sugar. 14 days after the operation the sugar began to diminish. In two months it was absent
26	52 years.	Noble (Beyea's case), discussion. *Vide* also Beyea's paper.	Multilocular pseudo-mucinous oöphoritic cystadenoma. Weight 22 pounds.	"	"	After the operation general treatment was adopted; four weeks after the operation there was only 4 per cent. of sugar Treatment was continued and in six months there was no sugar.	The urine contained 7 per cent. of sugar. All the symptoms of diabetes were present. The urine excreted by day contained from 60 to 80 per cent. of the total sugar excreted.
27	31 years.	Imlach.	Double pyosalpinx.	Appendages removed.	"		One month's history of thirst &c. Polyuria. Specific gravity of urine 1036; much sugar. Dieting, &c., reduced the urine to from five to six pints, with total quantity of sugar 2560 grains in the 24 hours. Three months later there were 1200 grains of sugar in the 24 hours. Operation performed. In a week the sugar had permanently vanished.

treatment reduced the percentage of sugar from 3·77 to 1. There was a marked increase in its amount after operation. Three epitheliomata of the lip have been successfully removed. In Fischer's case the patient was treated medically for about five months before operation to reduce the amount of sugar. In one of Reynier's cases an enlarged gland was removed at the same time; the resulting wound suppurated slightly. Five patients suffering from epitheliomata of the cheek or palate have been subjected to operation, two of whom recovered (the operation in one, however, was merely destruction of the growth with chromic acid). In one of the fatal cases a history of diabetes was only elicited on the occurrence of sloughing The cheek was slit to allow of free removal by the thermo-cautery Emphysematous gangrene appeared and it spread all over the head; 8 per cent. of sugar was discovered. In another case the patient succumbed to pneumonia on the fifth day after the removal of a growth involving the lower jaw; from 0·2 to 0·3 per cent. of sugar previously present disappeared under medical treatment. The third fatal case was that of an alcoholic patient whose urine contained 7·6 per cent. of sugar; pneumonia occurred and death followed from coma. Three operations for epitheliomata of the tongue have been recorded. In each the tongue was removed by the thermo-cautery and the patient recovered. Secondary hæmorrhage occurred in one case on the separation of the sloughs. Previous medical treatment was adopted in all. Tuffier quotes another instance in which 0·4 per cent of sugar was present before the operation, which disappeared under preliminary treatment. After the removal of the growth there was a slight attack of secondary hæmorrhage but the patient recovered. Smith and Durham undoubtedly correctly interpret this case as one of glycosuria secondary to ulceration of a new growth. Reynier records the excision of an eye with recovery. Diet caused the sugar to disappear. He also refers to the removal of a sebaceous cyst from the neck. The cyst was of the size of an orange. He does not state if preliminary treatment had been adopted. Two or three other sebaceous cysts have been removed with success, but the operations were so small that no notice is taken of them in this paper. Thus, of 16 cases 11 recovered, or a percentage of 68·75. Of the purely mouth and lip cases nine out of 12 recovered, yielding a percentage of 75. (*Vide* Table II.)

Operations on the Breast.

There are to be found in medical literature the records of 11 patients suffering from glycosuria who have undergone operations for malignant tumours of the breast. To these must be added two others operated upon by Mr. Willett, one at St. Bartholomew's Hospital and one in private practice, and one operated upon by Mr. Butlin. Further, Dr. Le Conte of Philadelphia has furnished by letter particulars of another case in which a recurrent scirrhus was twice removed; the first recurrence necessitated an extensive operation, with plastic work to close the wound. The percentage of sugar in this case reached, a few days after operation, the high figure of 11·5, but no special medical treatment was adopted. In Fisk's case a woman, aged 61 years, had an amputation of the breast performed for an ulcerated scirrhus in 1895. The operation was a complete one after the manner of Halsted. The urine contained 2·5 per cent. of sugar No preliminary treatment was adopted before operation. Ether was employed as the anæsthetic. Two weeks later the now granulating area was covered by Thiersch skin grafts. In March, 1898, a small recurrent nodule was removed from the scar under cocaine. The urine still contained sugar. In November, 1898, a small ulcerated patch was excised from the old scar, together with a piece of the underlying rib; she left the hospital with a granulating wound. The percentage of sugar was then 2 2. In August, 1899, she was still alive and well. In this case no special precautions were taken against coma nor is there any mention of the amount of ammonia excreted. Two of the cases were fatal, one from erysipelas (in 1881), which Smith and Durham do not consider to be a true case of diabetes but to be one of glycosuria consequent on the attack of erysipelas, though the amount of sugar is stated to have been high; the other from secondary septic infection of the track of the drainage wound on the fourteenth day. (The latter case occurred in 1882.) In six cases the glands were stated to have been removed. In at least three of the cases that recovered suppuration occurred. In the only male case of the series cellulitis and extensive gangrene of the skin over the side and back led to the discovery of diabetes but this quickly healed on the adoption of general treatment and carbolic acid internally. In no instance is there any mention of the amount of ammonia or of the use of sodium bicarbonate. Thus, of 15 patients 13 recovered. The number of operations performed upon them was 19, the percentage of patients recovering being 86 6 and the percentage of successful operations 89·47. (*Vide* Table III.)

Operations on the Female Generative Organs.

Three vaginal hysterectomies in the presence of diabetes have been performed for carcinoma (Professor Landau of Berlin having kindly furnished the notes of one unpublished case). In one instance the patient died comatose, coma being apparently induced by the anæsthetic. One of the others died eight months later from recurrence; general treatment at the time of the operation caused considerable diminution in the amount of sugar. The third patient was operated upon in December, 1900, by Professor Landau under chloroform. Convalescence was uninterrupted. The percentage of sugar was 3 in spite of a carbohydrate-free diet. A vaginal hysterectomy for procidentia was fatal on the sixth day from coma. Two abdominal hysterectomies for fibroids were quite successful; one was complicated by an umbilical hernia which was cured at the same time. In this case 5 per cent. of sugar previously present disappeared under appropriate treatment. An abdominal enucleation of a large fibroid was eventually successful though the wound did not run a quite aseptic course; the percentage of sugar in this case was uninfluenced by diet (unpublished case furnished by Professor Landau). Kleinwächter has recorded the removal of a polypoid fibroid per vaginam with a simultaneous curetting in a woman, aged 55 years, in whom the menopause had occurred five years before. She was corpulent and somewhat hysterical. There had been a suspicion of diabetes for five years. Whilst under observation the percentage of sugar varied from 1·4 to 3·2. Under diet and appropriate treatment at Karlsbad the sugar disappeared. Sugar was absent at the time of the operation to return a week later after an indiscretion in diet, the percentage being 3·5. A fortnight later it was still present Convalescence was complete. Giles has recorded the radical cure of umbilical hernia and the removal of a fibroid from the uterus of a woman with sugar in her urine. The sugar was quite transitory and may have been due to apprehension of the operation. It therefore will not be included in the statistics. Kleinwächter has pointed out in a recent paper that omitting Giles's case there are only nine instances of uterine fibroids complicated with glycosuria on record. With Landau's two unpublished cases the number rises to 11, of which four have been subjected to operation successfully. Reynier has recorded a "vaginal and abdominal" hysterectomy in which gaping of the wound occurred on the thirteenth day. Secondary suture, however, was effectual. The nature of the disease is not mentioned. Of five ovariotomies three were successful. One of the fatal cases was a patient with a bilateral ovarian dermoid with numerous adhesions which rendered the operation very difficult. The other fatal case was that of a patient with a malignant tumour of the ovary in which the wound on the fourteenth day gave way, allowing the intestines to protrude. Re-suture was not successful, death occurring on the fortieth day. Reference has already been made to two ovariotomies (and to a pyosalpinx) in which diabetic symptoms previously present vanished. This may have

TABLE V.—OPERATIONS ON THE MALE GENERATIVE ORGANS.

No.	Age.	Reference.	Disease.	Operation.	Result.	General treatment.	Remarks.
1	50 years.	Verneuil: Bulletin de l'Academie de Médecine, 1881	Epithelioma of the penis.	Amputation by galvano-cautery.	Fever next day (? malaria). Recovery.	For preceding 15 days. Sugar reduced to 0.	Slight diabetes. Total amount of sugar per diem 12 grammes. Reappeared the day after the operation.
2	62 years.	Smith and Durham (Jacobson's case).	Epithelioma of the penis; enlarged glands.	Amputation of the penis. A large operation, all the corpora cavernosa being removed.	Wound sloughed. The left foot became gangrenous. Death on the tenth day.	Diet and codeia slightly diminished the sugar.	Diabetes for 10 years. The patient was never quite himself after the operation. Albumin also was present.
3 a.	70 years.	*Claisse and* Durrieux	*Epithelioma* of the prepuce (of the size of a two-franc piece), phimosis.	Removal by a free circumcision.	Recovery.	—	Glycosuria for 10 years.
b.	—	(The same patient at 68 years of age)	Phosphatic calculus.	Lithotrity	”	—	—
4	65 years	Becker.	Epithelioma of the bladder; cystitis; stricture of urethra.	Suprapubic cystotomy.	Coma; death.	—	No sugar at the time of the operation; next day 7 per cent. Arterio-sclerosis. Post-mortem examination, ? coma precipitated by anæsthetic.
5	60 years.	St. Bartholomew's Hospital Surgical Register, vol. v, 1890, No. 1066.	Incontinence of urine; false passage.	Catheterisation under chloroform.	”	—	Specific gravity of the urine 1035; much sugar. Post-mortem examination, false passage; membranous urethra; ? coma precipitated by anæsthetic.
6	20 years.	*Fort.*	*Stricture of* the urethra.	Electrolysis October, 1882.	Recovery.	—	The same day polyuria appeared. *On the fourth day* the amount was eight litres. In spite of treatment about one kilogramme (?!) of sugar was excreted daily. Died April, 1883. *? Diabetes* induced by anæsthetic (chloroform).

the mucous membrane, although Cuneo has demonstrated the presence of lymphatics in this layer. Carcinoma selects by preference the lymph channels of the submucosa for its extension and it spreads by continuous growth and not by a metastatic process except in the rarest cases. This continuous growth is prolonged to the serous coat and so into the glands. Dr. Borrmann shows that in 20 out of his 63 cases of carcinoma of the stomach there was extension to the duodenum. He concludes that the pylorus offers no insuperable barrier, as has been supposed, to the extension of the growth, although this spread to the duodenum undoubtedly first occurs in the later stages of the disease. This conclusion is based largely on microscopical evidence. In discussing the morphology of gastric carcinoma the author thus classifies these growths: (1) carcinoma solidum; (2) cylindrical-celled carcinoma; (3) colloid carcinoma; (4) diffuse polymorphous-celled carcinoma; (5) malignant adenoma; and (6) mixed forms. He explains the structure of the malignant adenoma by the formation of a lumen inside the column of cells, the cells clinging to the walls of the lymphatic vessels. He does not recognise the so-called scirrhus as a group but he adds this term when it may be required. The malignancy of tumours is not always dependent upon their morphology. Dr. Borrmann recognises in general the relative innocence of the true cylindrical carcinoma and the malignancy of the diffuse colloid carcinoma. In carcinoma involving the mucous membrane the morphology does not justify the view that the growth has developed from any definite kind of cell of the glands in question. The author further adds that in the 2000 sections which he has examined he has never seen anything incompatible with the view that the cells grow into the lymphatic channels of the mucous membrane without the glandular elements being involved. The growth of the malignant adenoma takes place between the glands.

Throughout his book Dr. Borrmann lays great stress on the spread of carcinoma of the stomach by the lymphatics to the exclusion of extension by the veins, yet this more limited view is not by any means universally accepted. Thus M. Brault in the recent issue of Cornil and Ranvier's Pathology shows at some length that carcinoma spreads not only by the lymphatics but also by the venous channels.

The clinical section of the work is of great importance. In more than one-half of the cases (58 per cent.) both curvatures were involved in the malignant disease and generally to an equal extent, whereas in 30 per cent. the greater curvature and in 11 per cent. the lesser curvature were alone affected. Mikulicz has divided carcinoma more from the clinical standpoint into (1) carcinoma of the pylorus which nearly always encircles the organ; (2) carcinoma of the body which may occur in the greater or lesser curvature, but it may be circular when it extends to the pylorus; (3) carcinoma of the cardiac portion which is always situated on the lesser curvature; and (4) fundus carcinoma which is very rare.

Dr. Borrmann says that in 43 out of the 63 cases the tissues cut through in excising the growth were free from disease, as ascertained by the microscope, but that in 20 the incision had passed through diseased structures (cancerous). In nine of these 20 cases the diseased tissues were in the duodenum. The author concludes that in extensive carcinoma diffusely spreading and where the possibility of extension to the duodenum is present from three to four centimetres of the duodenum should be resected and in all other cases from one to one and a half centimetres should be taken away. It is quite impossible to see with the naked eye the fine outgoing processes from the new growth, hence wide resection is necessary. On the other hand, the author believes that total extirpation of the stomach is rarely called for. The glands and fatty tissue must be taken away. One possible source of error is admitted by the author in his investigation—viz., that the whole of the parts removed may not have been received by him, but after consultation with Professor Mikulicz he thinks that this could only very rarely have happened.

Rather meagre space is given to the question of recurrence and the author is somewhat dogmatic here. If the growth has been completely and radically removed then recurrence is, in the author's opinion, simply excluded. Presumably recurrence locally or in the glands only is referred to here. Of the 43 cases in which microscopically the cut ends of the resected stomach were found to be free from disease 28 patients are still alive and free from recurrence. Of the remaining 15, 11 died from the effects of the operation and four from recurrence in the glands. In view of these results Dr. Borrmann advocates the thorough removal of carcinoma of the stomach even in advanced cases.

Some comment is made upon the all-important subject of early diagnosis, but there are clearly limits to the possibility of early recognition of the disease, as in the case where the patient does not come under observation until the disease is considerably advanced owing to the symptoms having hitherto been trifling; also undue importance should not be attached to chemical tests, especially if they are not frequently repeated. It is difficult to do justice to the many points which Dr. Borrmann raises in this admirable monograph. The book is worthy of careful study, if only for the amount of excellent work which has been put into it.

LIBRARY TABLE.

First Annual Report of the Director of the Pasteur Institute of India, Kasauli. Lahore: Punjab Government Press. 1902. Pp. 32.—Hydrophobia is, as is well known, a scourge in India. Of wild animals the jackal and the wolf are very liable to be attacked and among the semi-wild pariah dogs the disease is also prevalent. The director of the Indian Pasteur Institute is Major D. Semple, R.A.M.C., and the institute over which he presides is the first one of the kind in the British Empire. It was opened at Kasauli on August 9th, 1900. Up to August 9th, 1901, there have been treated 321 persons for bites by rabid animals. Of these 29 were bitten on the head and face and one died; 228 were bitten on the naked skin in other parts of the body and two died; and 64 were bitten through the clothing and none died. Besides these deaths there were four of persons all bitten on a naked part of the body and all of whom died during treatment. They were all bitten by wolves on Dec. 29th, 1900, but did not arrive for treatment until Jan. 17th, 1901. There were also three patients, all bitten on exposed portions of the body, who died within 15 days from the last inoculation. These three and the preceding four patients are not reckoned as failures because their nerve centres became invaded by the virus of the original bites before treatment was completed. The report gives a very complete account of the method of preparing the virus. Nine other persons bitten by the same animals whose bites caused the seven deaths not reckoned as failures were treated at the same time and remain well; while four persons bitten by the same animals whose bites caused the deaths of the three failures were treated and also remain well.

London Matriculation Directory, January, 1902. Cambridge: Burlington House. 1901. Pp. 120. Price 1s. 6d.—This directory is issued under the auspices of the University Correspondence College and contains the calendar of that institution. The directory contains the matriculation regulations of the University of London, a list of text-books for, and the papers set in, the examination of January, 1902. Solutions to the papers are also given, so that the private student can test the accuracy of his work.

The School Calendar, 1902. London: Whittaker and Co.

been due to the relief of pressure, but Beyea has brought forward the suggestion that the sugar may have been caused by the absorption of material from the cyst and decomposition with excretion of sugar. In Table IV will be found details of six plastic operations for ruptured perineum or procidentia, the operation varying from a mere perineorrhaphy to more extensive work on the vaginal walls and abdominal hysteropexy. All recovered; medical treatment and diet were prominent features in most of them. (Dr. Baldy of Philadelphia has furnished with great kindness the notes of two unpublished cases.) Of two curettings one, in a young woman, was fatal, coma closing the scene on the third day. The other was for fungous endometritis. The cervix was sutured at the same time for an old laceration and some warts were removed from the vulva. Healing, though delayed, was complete. At St. Bartholomew's Hospital Dr. Champneys removed an epithelioma from the vulva of a diabetic whose urine contained 4·5 per cent. of sugar. At a subsequent operation enlarged inguinal glands were ablated, but the wound suppurated slightly on account of the removal of the dressings by the patient. 24 operations accordingly were performed on 23 patients with five deaths, the percentage of patients recovering being 78·25; of successful operations 79·16. The plastic operations were particularly successful. (*Vide* Table IV.)

Operations on the Male Generative Organs.

If septic cases and those of balano-posthitis be omitted

TABLE VI.—ABDOMINAL OPERATIONS OTHER THAN ON THE GENERATIVE ORGANS.

No.	Sex and age.	Reference.	Disease.	Operation.	Result.	General treatment.	Remarks.
1	Female; 58 years.	Barker.	Malignant tumour of the transverse colon.	Excision of the growth (four and a half inches of gut removed).	The wound did not run a quite aseptic course. Later a small slough formed in the mesocolon with temporary fæcal fistula. Recovery.	Adopted Codeine phosphate one grain subcutaneously. Diet. Bismuth carbonate as an intestinal antiseptic.	On the fourth day after the operation there was 6·6 per cent. sugar and on the ninth day 2 per cent. It was later reduced to a much less amount.
2	—	Barker.	Carcinoma recti. Complete obstruction.	Colotomy.	No repair of wound; death.	—	—
3	—	Naunyn, p. 452. (? by letter.)	Carcinoma of the stomach.	Gastro-enterostomy.	Death next day, *not* from coma.	Diet.	0 3 per cent. of sugar.]
4	Male; 50 years.	Fisk.	Acute appendicitis with symptoms of perforation on the second day.	On the second day the abscess was opened and the appendix was excised.	The wound healed slowly by granulation. Recovery.	—	Diabetes was known to have existed for several years. The abdomen was distended, tympanitic, and rigid. A lump in the iliac fossa.
5	Female; 60 years	Noble.	Ventral hernia.	Radical cure.	Recovery.	Codeine and strychnine.	18 months after the operation sugar was absent, general treatment being still continued. It was also absent three years later.
6	Male.	Barker.	Umbilical hernia.	".	Repair bad but eventually recovery.	—	Sugar previously absent reappeared on the day after the operation.
7	—	Reynier.	"	"	Slight disunion of the wound. Recovery.	—	Diabète gras.
8	Male; 17 years.	Fisk (unpublished case), by letter, 1901.	Irreducible pro-peritoneal hernia (right).	" (Bassini.)	Recovery perfect.	—	The sugar varied from 1·5 to 2·5 per cent.
9	—	Reynier.	Femoral hernia.	Herniotomy.	Recovery.	—	" Diabète athéromateux."
10	Female; 56 years.	Railton and Southam	Femoral hernia, strangulated.	Herniotomy under cocaine.	36 hours later coma. Death. (The coma was apparently induced by the shock of the strangulation.)	—	Under treatment for diabetes for the preceding two years. At the time of the operation there was an acetone smell, about the breath and pervading the room. Strong ferric chloride reaction.
11	Male; middle-aged.	Ashurst	Hernia, strangulated.	Herniotomy. The stricture divided.	The bowel at the time of the operation was gangrenous. The gangrene spread to the wound. Death.	—	Diabetes for a long time.
12	—	Reynier	Hernia of the bladder.	Radical cure.	Recovery.	—	Intermittent diabetes for years.
13	Male; 35 years.	Churton.	Pancreatic cyst with history of gall-stone colic.	Laparotomy and counter incisions Dec. 7th, 1892.	By July, 1893, the wound became a sinus. On Sept. 7th, 1893, the patient was re-admitted (he had been having insufficient food). Purpura on the legs and acetone in the urine. Much discharge from the wound. He went down hill and died on Jan. 8th, 1894. Post-mortem examination showed atrophied pancreas, rupture of the ureter, and free retro-peritoneal suppuration.		In spite of pancreatic diabetes he got over the immediate effects of the operation; but probably from the effects of bad diet, &c., sepsis gained the upper hand.
14	Male; 45 years.	Bull.	Pancreatic cyst; 10 months' history	Laparotomy July 19th, 1886; incised July 26th; 118 ounces evacuated.	Diet not restricted until the end of September. Codeine then administered. Much improvement; gained 12¼ pounds after the operation. The wound became a mere sinus. Died suddenly at the end of November, 1886.		Urine: from 100 to 140 ounces 5 per cent. of sugar.
15	Male; 40 years.	Pagenstecher.	Pancreatic cyst.	Incision and drainage Dec. 12th, 1878.	Became a mere sinus. Patient died one and a half years later from diabetes.		At the time of the operation 4·5 per cent. sugar was present in the urine

six operations remain which were performed in the presence of glycosuria. Three operations for epithelioma have been performed, with one death. The fatal case is mentioned by Smith and Durham. The operation was an extensive one—amputation of the whole penis. Sloughing of the wound and gangrene of the left foot brought about a fatal result on the tenth day. The other two operations were slighter, one (Claisse and Durrieux) being a mere circumcision for epithelioma of the prepuce following balano-posthitis. The patient had previously undergone lithotrity for a phosphatic calculus and had been diabetic for eight years. Becker in his paper on Anæsthesia in Diabetes refers to a fatal suprapubic cystotomy for cystitis complicating epithelioma of the bladder and stricture. Sugar was absent the day before the operation, but the day after it amounted to 7 per cent. The patient succumbed on the third day from coma. After a catheterisation under chloroform at St. Bartholomew's Hospital, a man, aged 60 years, died on the third day. The urine contained much sugar. Post mortem a false passage was found in the membranous urethra. In the last two cases the supervention of coma seems to have been due to the anæsthetic. Fort has recorded an interesting case in which, after electrolysis of a stricture in a young man, polyuria appeared the same day, the amount on the fourth day being eight litres, and in which there was over a kilogramme of sugar. In six months the patient died from diabetes. There had been no sign or symptom of diabetes previously to the operation. This case, taken in conjunction with some others that have been published, raises the question of the possibility of the induction of diabetes through an operation. (Compare the case in which ligature of the femoral artery was performed for aneurysm of the popliteal.) But it must always be remembered that diabetes may be latent. Thus of six operations on five subjects three died, giving an operation mortality of 50 per cent., but no special precautions had been taken in two against coma. (*Vide* Table V.)

Abdominal Operations other than on the Generative Organs or Bladder.

Two herniotomies for strangulated hernia have been published; both ended fatally. One patient, a woman, aged 56 years, was known to have been suffering from diabetes for two years. At the time of the operation there was an odour of apples about the breath which pervaded the room and the ferric chloride reaction was present. The herniotomy was done under cocaine; the next day the patient seemed better but coma followed and closed the scene in 36 hours after the operation. The other patient was a man in whom strangulation had existed for four or five days. At the time of the operation the gut was found to be gangrenous; it was therefore left in the wound, to which gangrene spread, the patient dying from sepsis. Barker has recently recorded three abdominal operations on diabetics. In one case four and a half inches of the transverse colon were removed for a malignant growth. The wound did not run a quite aseptic course and later a piece of the mesocolon sloughed, leaving a temporary fæcal fistula. Recovery, however, was complete eventually. General treatment was adopted but no sodium bicarbonate was administered. In another colotomy for complete obstruction was performed. No repair took place and coma ensued. The cause of the obstruction was carcinoma recti. The third patient underwent the operation for the radical cure of an umbilical hernia. Sugar, which had not been observed previously, appeared the next day. Repair was bad but healing eventually took place. A gastro-jejunostomy for cancer of the stomach proved fatal in two days, though not from diabetic complications; 0 3 per cent. of sugar was present. Fisk has recorded an appendicectomy in a man, aged 50 years, on the second day of an acute attack. The wound healed slowly by granulation. The patient had been diabetic for years (compare Table I., cases of temporary glycosuria accompanying appendicitis). Three pancreatic cysts in diabetics have been drained; in each case the patient survived the immediate effects of the operation but died some months after. In Churton's case the cyst was drained in December, 1892; the wound became a mere sinus by July, 1893, but under improper and poor diet out of hospital the health of the patient became worse and he was readmitted in September with a freely discharging wound. He went gradually down hill and died in January, 1894, 13 months after the original operation. Post mortem there was free retroperitoneal suppuration and the ureter was found to be ruptured. In Pagenstecher's case (mentioned by Körte) a man, aged 40 years, had a pancreatic cyst of the size of a child's head. The urine contained 4·5 per cent. of sugar. This was drained on Dec. 12th, 1888. On his discharge from hospital the wound was a mere sinus. Death from diabetes occurred one and a half years after the operation. In Bull's case an emaciated man, aged 45 years, in whose urine 4·5 per cent. of sugar was present, underwent laparotomy on July 10th, 1886, at which the cyst was fixed. It was opened and drained on the 26th, 118 ounces of fluid being evacuated. By Sept. 12th the patient had gained 12½ pounds in weight. Up to this date there had been no special dietetic or medical treatment, the percentage of sugar being 5. On the 18th he was dieted and was put on codeine. The percentage of sugar fell to 1·25. On Nov. 13th he left the hospital with a sinus two and a half inches deep. Two weeks later he died suddenly. There was no necropsy. He had discontinued diet and medicine on leaving the hospital. The number of pancreatic cysts recorded with sugar in the urine is quite small. These three cases show that even pancreatic diabetes is no bar to operation, though the final prognosis is less good if general precautions be neglected. Noble of Philadelphia has published an account of a radical cure of a ventral hernia in a woman, aged 60 years, the hernia being the sequela of the removal of the appendages some years previously. The amount of sugar in her urine diminished under the influence of codeine and strychnine. Recovery was complete. 18 months later her urine was free from sugar. Three years later she was still well though continuing general treatment. In a radical cure of an umbilical hernia recorded by Reynier slight disunion of the wound occurred but recovery followed. Two other radical cures by the same observer were successful. Dr. Fisk has kindly furnished the notes of a radical cure by Bassini's method for a pro-peritoneal hernia in a youth, aged 17 years. Recovery was perfect. The percentage of sugar varied from 1·5 to 2·5. This is the youngest diabetic patient upon whom an operation seems to have been performed. Thus, of 15 operations on 15 patients 11 recovered, which gives a percentage of 73 3. As, however, three cases were moribund or nearly so at the time of the operation the percentage of recoveries is unduly low. It must be remembered that several laparotomies are to be found in the section on operations on the female generative organs. There are also some cases in Class 1 in which, though apparently diabetic, yet after operation sugar permanently vanished. (*Vide* Table VI.)

(To be concluded.)

CASE OF POISONING BY MORPHIA INJECTION TREATED BY INFUSION OF SALT SOLUTION.

BY EDWARD F. WILLOUGHBY, M.D. LOND.

AT about 1 P.M. on Sept. 15th, 1901, I was called to see a woman who had, as I learnt, taken eight grains of sulphate of morphia in three hypodermic injections less than half an hour before. She had not acquired any tolerance, having had it administered on one occasion only, when it caused such violent sickness that she refused to have it repeated, preferring to endure the pain from which she was then suffering after an abdominal operation. I was soon joined by the locum-tenent of her ordinary medical attendant who was out of town, but he, being a young man, left the conduct of the case to me. On our arrival the patient was still semiconscious, but within 10 minutes she sank into a state of profound narcosis from which it was impossible to rouse her. During the first hour we administered three injections of one-fiftieth of a grain of sulphate of atropine and one-tenth of a grain of nitrate of strychnine without any perceptible effect, except that the strychnine excited spasms from every 10 to 20 minutes. The rigidity of the muscles, which lasted for from three to five minutes each time, greatly interfered with the artificial respiration which soon became necessary. We gave also at least a dozen injections of 20 minims of ether, with what benefit we could not say. The partner of the patient's own medical attendant joined us later, bringing a galvanic battery. Whenever we desisted from our efforts at artificial respiration the natural respiration ceased and it was four hours before we were able to discontinue it. Though by this time natural respiration was re-established and the spasms had passed off the patient's pupils were contracted to pin-points, her complexion was dusky, and the narcosis was so profound that the application of the strongest possible interrupted current to the soles of both feet did not excite the slightest movement even of the toes. She had not passed any urine and I drew off only about an ounce with the catheter. I then suggested the subcutaneous injection of the physiological salt solution as recommended first by Sahli of Berne. The partner was somewhat doubtful and averse to the procedure and was absent for an hour in quest of the apparatus. But when about a litre had been infused by gravitation into the subcutaneous tissue of the flank the effect was almost immediate and was striking. Within 20 minutes the duskiness and coldness of the skin had given place to a natural colour and warmth and the patient had so far recovered sensibility and consciousness as to struggle violently against the mechanical and electrical stimulation employed to keep her awake. She could answer questions intelligibly and she recognised the other medical men but she knew me to be a stranger and continually begged to be left alone.

I felt certain that the startling improvement following so soon after the subcutaneous infusion of 30 ounces of salt solution was owing to the impulse given by the increased intra vascular tension to the gastric and intestinal exudation and consequently to the elimination of the morphia, which ordinarily is excreted mainly in the bowel and little, if at all, by the kidneys; but that a certain proportion of the drug being probably re-absorbed the complete removal of so large a quantity would be long and tedious. I knew the action of potassium permanganate in the breaking up of morphia, even, as Dr A. P. Luff had shown, in the presence of oxidisable matter as vomit, and I should have had instant recourse to this antidote had the poison been swallowed. But it occurred to me that since the drug was now passing out into the alimentary canal it might be destroyed as fast as it appeared by contact with the permanganate and reabsorption might be prevented. I therefore mixed about a quart of a dilute solution, instructing the nurse to give the patient a wineglassful, alternately with her nourishment, every quarter of an hour or 20 minutes through the night until the contraction of the pupils had passed off. I did not see the patient again but was informed by her medical attendant that by 9 A.M. on the next day her condition was quite normal but for the sense of fatigue and soreness consequent on a score of hypodermic punctures and four hours of sustained artificial respiration.

In looking back on such a case one naturally asks oneself to which, if any, of the means employed the success was really due, which were superfluous, and whether any were useless or possibly even hurtful. We used hypodermic injections of atropine, strychnine, and ether, *secundum artem*, in deference to usage and because nothing could be taken per os, but I cannot honestly say that they were of any benefit except the ether which could not but act as a general stimulant. The respiration ceased again and again while the action of the atropine was visibly antagonising that of morphia on the pupils and the tonic contractions of the muscles caused by the strychnine made the work of artificial respiration extremely laborious. This alone kept the patient in life but that was all, for when at the end of four or five hours from the taking of the poison natural respiration seemed to be re-established she was still absolutely insensitive to pain or to electric shocks and deglutition was still impossible. The effect, however, of the saline subcutaneous infusion was such as to admit of no doubt and it was startling in the rapidity of its manifestation. So long as no fluids could be swallowed no urine was secreted and there was no reason why the morphia should be eliminated by the bowel until the intra-vascular pressure was raised by the infusion. Then, even, a long and anxious time, not wholly free from danger, would have ensued during which much of the drug would have been re absorbed and circulated again through the brain but for its destruction by the permanganate *pari passu* with its first elimination. In short, I look on the injections as useless, on the artificial respiration as having served to keep the patient alive until means could be taken for washing out the poison, the saline infusion as having effected this, and the permanganate as having greatly aided the result by preventing re-absorption.

Green Lanes, N.

AN INTERESTING PHENOMENON OCCURRING IN TACHYCARDIA.

By HERBERT D. EVERINGTON, M.B., L.R.C.P. LOND., M.R.C.S. ENG.,

LATE RESIDENT MEDICAL OFFICER, ROYAL HOSPITAL FOR CHILDREN AND WOMEN, WATERLOO-ROAD, S.E.

A MARRIED woman, aged 36 years, was admitted into the Royal Hospital for Children and Women Waterloo-road on August 3rd, 1900, suffering from articular pains and swellings which she had had for some days previously. On admission she looked decidedly ill. The face was puffy and congested, the tongue was dry and furred down the centre, and the pulse was of full volume, high tension, and "bounding," the beats numbering 128 to the minute, no irregularity being noted. The temperature was 103° F. Nothing abnormal was found in the chest or the abdomen. The left knee and wrist were acutely tender and were much swollen. The patient was placed on a diet of milk and was given 10 grains each of the bicarbonate and salicylate of soda with half a drachm of sal volatile every four hours. Her condition remained much the same for some days and on the 7th the alkaline salicylate mixture was replaced by doses of 10 grains of salicylic acid given in cachets every six hours. The diet was made more generous. Up to the 9th no undue acceleration of the pulse was noted the range varying more or less with the temperature from 92 to 112 per minute. On the night of the 9th, however, this moderate pulse-rate had given place to one of extreme rapidity. The frequency could no longer be counted at the wrist, the pulse being too rapid and "running." By means of the stethoscope, however, over the heart the beats could be distinguished and were found to number 224 to the minute. No complaint was made with reference to the heart though the patient complained of the pain in the limbs. The salicylic acid was immediately discontinued and five minims of tincture of digitalis with 30 minims of sal volatile were given and repeated every four hours. During the early hours of the morning the pulse maintained an extremely rapid rate and was numbering 210 when the morning round was made. A prescription was ordered containing 10 minims of tincture of digitalis, five minims of tincture of nux vomica, half a drachm of aromatic spirit of ammonia, 10 minims of spirit of chloroform, and distilled water to make up one ounce. This was given every four hours. On the afternoon of the 10th the patient was examined by Dr Guthrie Rankin who found no evidence of organic disease of the heart and no dilatation whatever. The heart beats were counted at about 220 per minute. During his examination Dr. Rankin ordered the patient to take deep breaths and after several of these inspirations it was found that the heart beats had dropped to 124 in the minute, or roughly a fall of 100 beats. A mixture of 15 grains each of the bromide and salicylate of sodium was given every four hours, alternating with the digitalis mixture above mentioned. The pulse was not noticed to be unduly accelerated for several days but the temperature remained high, averaging 100°. The bromide was discontinued on the 18th. The patient gradually went down hill and the tongue became extremely dry and foul, sordes developing on the teeth and lips. On the 22nd she presented a decidedly "typhoid" appearance. Soon after midnight on the 25th the pulse had again risen and it numbered 192 per minute. On taking some deep breaths the rapidity fell immediately to 108. On the night of Sept. 2nd tachycardia was again present—202 beats per minute—but this time the rapidity could not be reduced by deep inspirations as heretofore, nor did they have such an effect subsequently. The patient lost ground continually. On the 5th the highest rate of pulse was noted, the beats numbering no less than 234 per minute at 2.25 P.M., when the temperature was 103°. From being in an extremely critical condition the patient began to show signs of improvement and by the 24th she was out of immediate danger. No further tachycardia was recorded. The knee and wrist improved but never returned to their natural state. The patient's general health became very much better and she finally left the hospital in December.

There are one or two extremely interesting points in connexion with this case. Leaving on one side the question of diagnosis of the articular trouble which presented much difficulty and turning to the condition of tachycardia the case adds further evidence to the already noted fact that alteration of intra-thoracic pressure may influence attacks of heart-hurry. In the above patient the mere mechanical taking of deep inspirations was sufficient to reduce the frequency of the heart-beats by nearly 100 per minute. How this does so is not very evident, but that the dynamical alteration has such an effect is a recognised fact. Sir William Broadbent in his treatise on "Heart Disease" states that "to arrest an attack of palpitation it is sometimes only necessary to take a dozen deliberate breaths." Again, in Dr. Thomas L. Stedman's "Twentieth Century Practice of Medicine," vol. iv., p. 413, Rosenfeld is quoted as describing how a patient made the accidental discovery that after a deep breath the attack of palpitation ceased. Rosenfeld tried increased intra-thoracic pressure as treatment for this condition and with much success. Dr. T. Clifford Allbutt in his "System of Medicine" quotes a case in which, by holding the breath in inspiration and bending down and thereby pressing the abdomen on the thighs, the attack of palpitation was arrested. The high rate of frequency of the heart-beats is an interesting feature in the case described above which, though not as great as some that are recorded, is yet sufficiently remarkable to deserve attention.

Sanderstead, Surrey.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF ECLAMPSIA OCCURRING IN TWIN PREGNANCY.

By William B. Mason, M.R.C.S. Eng., L.R.C.P. Lond.

The following case is one which is chiefly remarkable for the number of the fits and for its resulting in complete recovery. The patient was 26 years of age and was married on April 27th, 1901. Menstruation commenced when she was 19 years of age; it was always painful but regular. She never had any fits. When a child she contracted scarlet fever but had no hæmaturia. She suffered from anæmia. In June, 1899, she had an attack of hæmatemesis. There had been amenorrhœa since marriage. On two occasions—namely, on Oct. 30th and Dec. 2nd, 1901—she sent messages to the effect that she was feeling pain in the abdomen. On examination it was found that there was slight general tenderness over the abdomen; it was relieved each time by fomentations. There was no discharge from the vulva and the temperature was not raised. Labour commenced on Feb. 19th, 1902, and was rather long but quite normal up to the protrusion of the head of the first child. When the perineum was stretched to its utmost the patient's legs were noticed to stiffen and a regular eclamptic fit then followed. First there was a tonic stage when her head was turned to the right with the eyes wide open and staring; then her whole body stiffened, producing opisthotonos or pleurosthotonos, according to her position at the time. This stage lasted about three seconds and was then followed by a clonic spasm of all the muscles of the body with production of snoring respiration. After this first fit she regained consciousness in about half an hour and asked if "it would soon be over." As she did not know that there was a second child I told her that it would not be very long now. During the birth of the second child exactly the same thing happened and this fit lasted about the same time as the first. Both children were very small and were delivered without any difficulty. As soon as the third stage was completed I gave a hypodermic injection of one-hundredth of a grain of hydrochlorate of cornutin followed by an injection of one-hundredth of a grain of hydrobromate of hyoscine. As the patient was still having fits in very rapid succession I repeated the hyoscine in one hour's time. After this she slept for four hours and had no fits but when she awoke the fits recommenced. I ordered the following mixture to be taken every two hours: 15 grains of bromide of potassium, one drachm of tincture of hyoscyamus, and syrup of ginger and chloroform water to make up half an ounce. I also directed half a drachm of chloral hydrate to be dissolved in an ounce of water and injected per rectum. Under this treatment the fits became less severe and less frequent, but they nevertheless continued for five days, during which time she had 62 in all and as many as 20 on the third day. During the whole of the five days urine and fæces were passed unconsciously and as soon as some urine could be collected it was found to become quite solid when heated to the boiling point. The patient's temperature was normal throughout. After the fifth day convalescence was uneventful. One of the infants died from inanition on the fourteenth day. The mother got up on the twentieth day and is now quite well except that her memory is slightly deficient. I saw the other infant as recently as April 21st and I do not think that it will survive long.

Southsea.

A CASE OF INTRACTABLE NASAL HÆMORRHAGE.

By G. Hunter Mackenzie, M.D. Edin.,

SURGEON TO THE EYE, EAR, AND THROAT INFIRMARY, EDINBURGH.

On Dec. 29th, 1901, I was asked by Dr. James Mill of Leith to see a case of nasal hæmorrhage of about one week's duration which had proved refractory to the usual methods of treatment. The patient was a man, 49 years of age, rather alcoholic and with slight albuminuria. On examination of the right nostril the seat of the recent bleeding was readily located, as is usually the case, on the anterior third of the septum, about one centimetre above the nasal floor. Under cocaine the hæmorrhagic area was freely galvano-cauterised and a pledget of cotton-wool saturated with a solution of adrenalin chloride was inserted. This treatment proved ineffectual, for on the following day I was again asked to see him on account of frequent recurrence of the bleeding. The cauterisation and applications of adrenalin were repeated over a wider area of the septum and during this process the patient became unconscious and had a convulsive attack. He was assisted to bed, when the hæmorrhage again commenced in a more intense degree than ever. He continued to bleed very freely for the next 24 hours, with the result that his condition became so extremely serious that we had him removed to the Edinburgh Eye, Ear, and Throat Infirmary. Further local treatment having proved unsuccessful, on the morning of Jan. 1st, 1902, chloroform was administered by my colleague, Mr. John Cumming, and with a nasal spoon and curette I stripped off the whole of the mucous membrane of the septum. Very profuse hæmorrhage accompanied this procedure but it soon ceased spontaneously. On the night of the 2nd (34 hours after the curetting) the patient had a moderate bleeding and on the morning of the 4th there was a very slight recurrence. I was fortunately present on the latter occasion and on examining the patient I found that the blood was oozing very slightly from the roof of the nostril in close contiguity to the septum, an area from which the mucous membrane had not been removed. As the bleeding was extremely slight I did not consider further treatment to be necessary. From that date to this (May) there has been no further hæmorrhage and the patient has quite recovered his former good health.

As, so far as I know, this is the first instance in which severe nasal hæmorrhage has been treated by curetting the mucous membrane I have thought it fit to put it on record.

Edinburgh.

A CASE OF INFECTIVE PERIOSTITIS.

By Walter H. Haw, M.R.C.S. Eng., L.S.A.

In The Lancet of March 1st, 1902, p. 589, I notice a clinical note upon a case of infective periostitis by Mr. John R. Griffith. As I have lately attended a patient whose symptoms were in many respects similar to those described in that note a brief record of the case may be of some interest.

On Feb. 25th 1902, I was called to see a little girl, aged 11 years, with the following history. On the 23rd she was apparently well until towards evening, when she complained of chilliness and pain in the left hip but she was able to go to church in the evening. Next day the pain was worse and when I saw her on the 25th she lay in bed on her back evidently in great pain and with an anxious look on her face. Her temperature was 104° F. and her pulse-rate was 120; her tongue was furred but moist. She complained of pain in the region of the left hip and on examination I found that there were swelling and resistance in the area lying between the crest of the ilium and the trochanter and also excessive tenderness to touch and movement. The cutaneous veins coursing over the area of swelling were enlarged. In my opinion the case was one of suppuration in connexion with the iliac bone but I could find no superficial focus from which it could have arisen. There was, however, the mark of a recently healed injury on the left foot but there was no pus. On the previous night she was said to have been slightly delirious and she then stated that her leg was sore because one of the children had been lying on her. Further, it was remembered that on the 20th she had fallen from a tree but I could not directly connect the pain in the hip with the fall. On the 27th her condition suggested cerebro-spinal meningitis, there being pain and acute tenderness over the body generally, rigidity of the posterior muscles of the neck, and delirium and unintelligible speech, while the urine and fæces were passed in bed. On March 2nd these symptoms had disappeared but it was reported that the abscess had burst and on inquiry I found that this idea was due to a purulent light yellow discharge from the vagina. On the 4th it was further reported that the bruise due to the fall was at last coming out; this turned out to be a dusky red discolouration over the seat of pain and resistance with a similar flush upon the left olecranon process. On the left front of the abdomen were some red streaks of lymphatics radiating from a soft, subcutaneous, rose-coloured tumefaction of the size of a sixpence. No fluctuation could be obtained over the seat of trouble but in view of the infection of the blood I cut down upon the ilium and evacuated about two ounces of pus which did not flow until the periosteum was divided. A drainage-tube was inserted and injections of potassium permanganate were employed but no improvement whatever resulted, the case going from bad to worse. On the 6th the left cheek swelled but no pus was detected in it and on the back of the left heel appeared a red patch with purulent foci dotted over the surface. Death occurred in the early morning of the 7th.

The points of interest to me in this case were: (1) the history of a fall; (2) the presence of a yellow vaginal discharge; and (3) the temporary acute involvement of the cerebro-spinal system, due probably to the formation of a cerebro-spinal poison at the seat of suppuration. How far the vaginal discharge was to be connected with the statement made by the patient during slight delirium that a child had been lying on her I cannot say. I made no inquiries in this direction, for I looked upon the discharge at the time as part of the general infection of the blood.

Knysna, Cape Colony.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Professor Virchow has announced that he will not be able to give any lectures during the present summer session; the anatomical and microscopical demonstrations will be given by the assistants—viz., Professor Jürgens, Professor Israel, and Dr. Oestreich.—*Cracow*. Dr. Emil Godlewski has been recognised as *privat-docent* of Anatomy and Embryology.—*Ghent:* The chair vacated by the death of Professor Bouqué is to be divided into a chair of General Surgical Pathology to which Dr. van Imschoot has been appointed and a chair of Special Surgical Pathology which has been given to Dr de Cock.—*Griefswald*: Dr. Fritz Moritz of Munich has been offered the chair of Medicine in succession to Dr. Krehl, who goes to Tübingen.—*Munich:* Dr. Friedrich Müller of Basle has been appointed to the chair of Medicine, known as the second, which has been held by Professor Joseph von Bauer.—*Naples:* Dr. Achille Capaldi has been appointed to the chair of Gynæcology.—*Philadelphia (Polyclinic):* Dr. Joseph Sailer has been appointed Professor of Diseases of the Stomach and Intestines.—*Prague (Bohemian University):* Dr Carl Chodunsky has been promoted to the Ordinary Professorship of Pharmacology and Pharmacognosis. (*German University*): Dr. Alex. Margulies has been recognised as *docent* of Psychiatry.—*Rome* Dr. Michelangelo Luzzato has been recognised as *privat-docent* of Medical Pathology.—*Turin:* Dr Alfonso Cattaneo has been recognised as *privat-docent* of Ophthalmology.—*Vienna:* Dr. Rudolf Matzenauer has been recognised as *privat-docent* of Dermatology.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN, WATERLOO-ROAD.

A CASE OF TRANSPERITONEAL NEPHRECTOMY FOR SMALL ROUND-CELLED SARCOMA IN A BOY, AGED FOUR YEARS.[1]

(Under the care of Dr. C. O. HAWTHORNE and Mr. H. J. CURTIS.)

THERE can be no doubt that early nephrectomy is the only treatment for sarcoma of the kidney in infants, even though the mortality from the operation is over 50 per cent. and though statistics show that of the cases which recover 90 per cent. die from recurrence within a year.[2] In the following case it would have been of interest to have had a bacteriological examination of the pleuritic fluid, as that might have explained the occurrence of the pleurisy from which the patient died.

A boy, aged four years, was taken to the Royal Hospital for Children and Women on Oct. 7th, 1901. He was then the subject of a considerable abdominal tumour which, without much difficulty or hesitation, was recognised as a growth arising from the region of the left kidney. The enlargement of the abdomen was accompanied by undue prominence of the superficial veins and had only been recognised by the boy's mother as recently as Sept. 23rd, though it was allowed that the patient's health had not been satisfactory for a period of two months It appears that the boy accidentally fell when running in the street on August 5th and that subsequently to this he had never seemed quite well. This fall had the fortunate consequence of securing for Dr. Hawthorne and Mr. Curtis a knowledge of the boy's condition two months before he came under their own observation, as on August 7th—that is, two days after the accident—he was admitted to St. Thomas's Hospital. Through the courtesy of Mr. P. W. G. Sargent they learnt that on that date the boy was reported to have been continually sick and fretful since his fall; that on examination he was noted to keep his legs drawn up on the abdomen; and that there was dulness on percussion with marked tenderness in the left lumbar region. In the course of the next day or two, however, the boy lost all his symptoms and he was discharged apparently well on August 10th. From this date until the mother's discovery of the abdominal swelling in the latter part of September there appear to have been no symptoms of a definite character. The boy seemed to be weak and listless, and perhaps had lost flesh but he made no complaint of pain. At no time was blood observed in the urine, there was no albuminuria either when the urine was examined at St. Thomas's Hospital or at Waterloo-road, and vomiting was limited to the two or three days immediately after the accident.

On admission the patient was a thin and delicate-looking boy, very quiet, but not complaining of pain or other discomfort, and in the course of a few hours he seemed to be quite at ease, sitting up in bed and playing with toys, apparently entirely unaffected by the presence of the tumour. The family history presented nothing of interest. On examination, the superficial veins over the left flank were seen to be enlarged but there was no œdema of the abdominal wall. A hard, irregularly-rounded swelling could be felt amost half filling the abdomen, occupying chiefly the left flank. Above the umbilicus it crossed the middle line and reached nearly to the right linea semilunaris. Below the umbilicus the tumour did not extend quite as far as the middle line. Its smooth, rounded lower border dipped just below the iliac crest. No notch could be felt anywhere. The swelling did not move with respiration. Though generally of very firm consistence, in places it seemed to be soft and almost fluctuating. Its median half was resonant on percussion, the descending colon evidently lying over it. The urine was of normal colour, with a specific gravity of 1026; it gave an acid reaction and contained no albumin. The chest was normal. The temperature on admission was 96·6° F., rising three days later to normal.

---

[1] A paper read before the Society for the Study of Disease in Children on April 18th, 1902.

[2] J. Bland Sutton: Tumours, second edition, p. 134

Transperitoneal nephrectomy was performed four days after admission, the tumour, with the involved left kidney, being shelled out with a good deal of difficulty owing to the firm adhesions to the posterior abdominal walls (especially over the lower half of the back of the growth) and to the tail of the pancreas. There was in consequence considerable shock, but very little hæmorrhage. The ureter at its origin was completely concealed in the growth. The tumour removed weighed three pounds 15 ounces. It was firmly encapsuled and measured about six and a half inches from above down and six inches from side to side. After recovering from the immediate collapse there was persistent vomiting, feeding having in consequence to be almost entirely rectal. Otherwise, during the first week the patient seemed to be doing well, the temperature remaining normal. Five days after the operation the child began to suffer from cough. The temperature was 98·8°; the pulse was 136 and the respirations were 28 per minute. The chest was normal. The wound closed, but owing to the persistent vomiting and the onset of cough the stitches were not removed before the eleventh day. The patient unfortunately developed pleurisy with effusion on both sides and died on the fifteenth day after the operation.

The state of the urine was as follows:—On the same evening as the operation the amount of urine passed was four ounces and the same amount was passed the next day, the specific gravity being 1030; it gave an acid reaction; there was no albumin. On the second day after the operation about 14 ounces of urine were passed but all of it could not be collected. On the next four days the amounts collected were 11 ounces, six ounces, four ounces, and 13 ounces respectively. On the last of these days the specific gravity was 1028; the reaction was acid; there was no albumin or sugar. On subsequent days the following amounts were collected: five ounces, four ounces, 10 ounces, eight ounces, eight ounces, seven ounces, and eight ounces, the bowels at the same time acting freely, once or more a day.

Necropsy.—At the post-mortem examination the wound was found to have united throughout. There was no evidence of peritonitis. There were a few adhesions of the intestine to the parietal peritoneum where it had been divided in order to shell out the kidney tumour, the divided peritoneum having apparently readily united. So far as the nephrectomy was concerned the condition seemed to be perfectly satisfactory, the entire growth appearing to have been removed. There were no secondary growths or enlarged lymphatic glands. The right kidney and the liver were normal. On opening the chest a considerable quantity of fluid was found on both sides, especially on the left side. There was extensive pleurisy on both sides from the apex to the base. Section of the lungs showed them to be practically normal. No secondary growths were present in the brain or elsewhere.

Description of the tumour removed.—A median section through the growth and kidney showed the tumour, as so frequently happens, to be arising from the connective tissue within the hilum of the kidney, the cortex of which, measuring nearly seven-eighths of an inch, presented a fairly normal appearance. From the smooth, rounded appearance of the tumour, as it lay in contact with the cortex of the kidney, it seemed evident that the pelvis, though distended with growth, was still intact. A slit-like cavity in the region of one of the pyramids suggested dilatation of one of the calyces from back pressure. The upper end of the ureter was embedded in the growth. The tumour was limited by a double capsule, that of the kidney proper and of the perinephric fat, the two layers being for the most part intimately blended and of a dense white colour and very firm appearance. The cut surface of the growth was somewhat fibrous-looking, white, and homogeneous, but there were numerous areas of bright-red blood extravasation. There did not appear to be any cystic degeneration. When quite fresh the growth was very soft, granular, and extremely friable, readily escaping on slight pressure after incising the capsule. *Microscopically*, the tumour was a small round-celled sarcoma, rounded masses of sarcomatous tissue containing many new vessels lying embedded in a well-formed stroma of connective-tissue fibre, which only here and there showed any tendency to develop into spindle cells. A very few tubules, probably derived from glands in the hilum, could be seen surrounded by the round-celled sarcomatous elements.

Remarks by Dr. HAWTHORNE and Mr. CURTIS.—The chief interest of the above case is to be found in its surgical aspects. Though a favourable issue cannot be recorded there is no reason to regret that operation was undertaken. In it there resided obviously the sole chance of prolonging or saving the patient's life and the fatal event arose from an unfortunate complication which, so far as can be judged, had no immediate or direct connexion with the operation.

Such a soft, vascular, rapidly-growing, round-celled sarcoma as was present in this case is the most common variety of all and composed 23 out of 43 tumours of the kidney operated on in children since 1890, according to Henry Morris. As is well known, untreated malignant renal tumours are rapidly fatal in children, death following soon after the tumour has become obvious. As regards the diagnosis, it must be remembered that in children pain is often absent, and hæmaturia is also absent in three-fourths of the cases of malignant tumours of the kidney (Tuffier).[3]

Early diagnosis and operation before invasion of the tissues around, and especially of the lymphatics, are essential for the diminution both of the operation mortality and of the liability to recurrence. Nephrectomy is useless in cases where the glands and other tissues around are infiltrated with secondary growth, and should this be found on making an exploratory laparotomy through one or other linea semilunaris the operation should be abandoned.

It is noteworthy that though the first successful nephrectomy in a child was done only in 1877 by Jessop and the operative mortality up to 1890 was as high as 60 per cent., since 1890 the mortality has been reduced two-thirds, so that in 1898 it was only 17 per cent. Albarran has collected 11 cases of children known to be free from recurrence and in good health at periods varying from one to two and a half years after the operation (Henry Morris). The advisability of surgical interference until recently was open to doubt; but two successful nephrectomies by Abbé in 1892, mentioned by Henry Morris,[4] are so interesting and go so far to settle this vexed question, that we venture to quote them in full, though a considerable number of successful cases have also been recorded before and since the date above mentioned. D. R Abbé records in the *Annals of Surgery* of Nov. 22nd, 1895, two cases of round-celled sarcoma of the kidney, one containing a good deal of involuntary muscle, cured by nephrectomy. The patient in the first case was a girl, aged two years, who was operated upon on April 12th, 1892. The weight of the tumour was two and a quarter pounds. She was quite well at the age of five years. In the second case the patient was a girl, aged 14 months, who was operated upon on Nov. 20th, 1892. The weight of the tumour was seven and a half pounds, or just one half the weight of the child immediately after the operation. She was alive and quite well in April, 1895.

One other feature of the present case is worthy of note and it arises from the history of a fall some six or seven weeks before the detection of the tumour. Such a history, of course, raises the question whether injury can reasonably be held in any way responsible for the development of the tumour. The apparent association between traumatism and the eruption of sarcomatous growths has often been observed. In a recent paper[5] Dr. W. B. Coley, summarising his experiences, states that in his entire series of 270 cases 86, or 31·8 per cent., gave a history of injury, and that in 31, or 11·5 per cent., the tumour developed almost immediately after the injury. Whatever significance may be attributed to it the fact remains that in the present case the patient within two months after a fall, and when physical examination failed to detect anything definitely abnormal, was found to be the subject of a sarcomatous tumour arising from the left kidney and reaching nearly four pounds in weight.

MEDICAL SOCIETY OF LONDON.

The Latent Period in Grave Abdominal Inflammation.—Bilharzia in its Clinical and Pathological Aspects.

A MEETING of this society was held on April 28th, Dr W. H. ALLCHIN, the President, being in the chair.

Mr A. H. TUBBY read a paper on the Quiescent or Latent Period in the Course of Grave Abdominal Inflammation, which is published at p. 1305 of our present issue.—Dr T. D. SAVILL referred to the importance of the subject both in its medical and surgical aspect and confirmed the value of the pulse-temperature ratio as an indication of gravity. The temperature was often subnormal in these latent abdominal cases but if the pulse was persistently rapid, say over 100, the case called for further investigation and prompt surgical aid. His experience did not lead him to attach so much importance to the actual number of leucocytes present as an indication of suppuration as the proportion of polynuclear cells to the other white cells. Normally this was 65 per cent. and no obscure pus formation could occur without an increase in this proportion. Blood films which could be easily stained and examined should always be investigated in latent abdominal affections of the kind referred to by Mr Tubby.—Dr J. H. BRYANT was glad that Mr Tubby had drawn attention to the importance of leucocyte counts in the diagnosis of obscure abdominal suppurations. He lamented the fact that so little was done in this country in the way of systematic blood examination and pointed out that at the Johns Hopkins Hospital in America systematic and thorough investigations of the condition of the blood were made in every case admitted irrespective of the diagnosis. He alluded to some cases of appendicitis under his (Dr Bryant's) own care in which the presence of leucocytosis had been an indication for surgical interference and an absence of leucocytosis a contra-indication. The importance of the rapid pulse-rate as an indication for operation he fully endorsed. A slow pulse with a high temperature in his experience had rarely if ever been associated with any form of latent abdominal suppurative disease which had required the surgeon's aid. With regard to the presence of chest complications as an indication for operation he pointed out the great difficulty of distinguishing diaphragmatic pleurisy and basal pneumonia from primary abdominal disease on account of the occasional immobility of the diaphragm and the presence of severe abdominal pain and tenderness in the former conditions.—Mr JONATHAN HUTCHINSON, jun., remarked that there were two classes of quiescent phases, one in which it came on before and the other in which it came on after the more marked signs of abdominal disorder. These required different interpretations and he referred to a case in illustration. The explanation of this latent phase by derangement of the nerves of the intestine did not always obtain. Rigidity of the muscles was not by any means an infallible sign of peritonitis. As to leucocytosis the results seemed to differ in the hands of different observers.—Dr F. DE HAVILLAND HALL referred to the question of the diagnosis of diaphragmatic pleurisy and appendicitis. In some cases of appendicitis the diaphragmatic lesion was evidently, from its symptoms, of a peritoneal nature.—The PRESIDENT congratulated Mr Tubby on having formulated so many points of importance in these cases. Short of laboratory methods the character and rate of the pulse were the most important symptoms. It had been drawn attention to by Dr H. A. Caley some years ago.—Mr TUBBY in replying suggested that the frequent involvement of the diaphragmatic peritoneum in abdominal cases was accounted for by the copious distribution of lymphatics in this region. This also explained its greater vulnerability as compared with the peritoneum for instance of the pelvis.

Lieutenant P. S. LELEAN, R.A.M.C., made a communication on the Bilharzia in its Clinical and Pathological Aspects illustrated by lantern slides and microscopical preparations. After dealing with the morphological relations of this parasite its development was fully discussed. He had demonstrated the actual hatching of an embryo in blood serum kept for 24 hours at a temperature of 30° C. This coupled with the observation of an embryo hatched in undiluted urine established two most important links in the chain of events possible in auto-infection. The hatching of bilharzia ova in serum had been previously regarded as impossible and it completely removed the main objection which had been urged against Sonsino's theory of auto-infection. The adult worm was only found in the portal system but the embryos migrated and might be found anywhere. When death took place it was usually due to pneumonia. The channel of infection was next discussed. The invasion of the parasite through the urethra during bathing was possible, but the evidence pointed to its entry per rectum, thus gaining access to the portal system which was the habitat of the adult worm. The disease was very rare in women who in tropical countries bathed as often as men. Turning to the subject of treatment Lieutenant Lelean regarded three remedies as of value. Urotropin was useful especially for the cystitis and hæmaturia, but benzoic acid and methylene-blue seemed to have more direct effects on the parasite and produced an amelioration almost amounting in some cases to cure. His (Lieutenant Lelean's) practice was to administer every fifth day four grains of methylene blue three times a day for one or two days and benzoic acid in the interval.—Surgeon General A. KEOGH, A.M.S., referred to the growing importance of the subject, because a number of cases would certainly be coming home from South Africa. Such cases were liable to be mistaken for other causes of hæmaturia. A number of cases of so-called dysentery were really bilharzia.—Colonel W. L. GUBBINS, R.A.M.C., remarked that nearly all the cases which he had seen in Pretoria of bilharzia came from one district in the north east portion of the Transvaal.—Dr BRYANT had had three cases under his care in England this year. All had been treated with urotropin without much success, but one case treated with carbolic acid was successful.

PATHOLOGICAL SOCIETY OF LONDON

A New Pathogenic Bacterium resembling Bacillus Pestis.—The Action of High Frequency Currents on Bacteria.—A case of Aneurysm of the Heart.—A case in which a Hat pin remained Embedded in the Heart during Life.—An Epidemic simulating Tuberculosis in Guinea-pigs.—Specimens showing the Results of Experimental Yeast Infection.—The Inhibitory Action on Bacteria of the Fluid from Charcot Joints.—A Method of Demonstrating the Track of Bullet Wounds of the Brain.

A MEETING of this society was held in the laboratory of the Middlesex Hospital on May 6th, Mr W. WATSON CHEYNE, the President, being in the chair.

Dr E. KLEIN exhibited lantern slides and cultures of a bacillus which he had found in the dead bodies of rats which resembled the Bacillus of Plague (bacillus pestis) in its morphological features and in its pathogenic qualities but which differed from that organism in its cultural qualities.

Mr ALEXANDER G. R. FOULERTON and Dr A. M. KELLAS read a paper on the Action on Bacteria of Currents or Discharges of High Potential and Rapid Frequency. The results were given of some preliminary experiments made at the commencement of a systematic investigation into the action of such currents on various micro-organisms. The experiments, as a rule, were carried out by "spraying" the current over the surface of an emulsion in water of the bacteria tested. The current was applied by means of a platinum brush; a platinum wire was sealed through the bottom of the tube containing the emulsion by means of which the current was either carried to earth or discharged into the air. The experiments were carried out at a temperature of from 15° to 16° C. The voltage varied from 35 to 24 and the current from 2·5 to 5 ampères. Small quantities of nitric acid and ozone were probably carried into the emulsion which became acid in reaction. But these substances probably did not materially influence the results obtained. The bacteria which had been tested were bacillus typhosus, bacillus coli communis, bacillus dysenteriæ (Flexner), bacillus anthracis, bacillus pyocyaneus, bacillus prodigiosus, staphylococcus pyogenes aureus and streptococcus pyogenes. In the case of bacillus anthracis (sporing culture) a certain proportion of the bacteria present were destroyed by exposure to the current for 20 minutes and the emulsion was sterilised by an exposure for 45 minutes. In the case of bacillus dysenteriæ the emulsion was sterilised by an exposure for 30 minutes, but for these two species the exact lower limit had not been determined. Emulsions containing the other bacteria were sterilised by exposures of from 10 to 20 minutes' duration.

Mr. T. J. Bokenham also reported observations which he had made on the Action of High Frequency Currents on the following series of micro-organisms—all suspended in watery emulsion—bacillus typhosus, bacillus anthracis (asporogene), bacillus diphtheriæ, streptococcus pyogenes, and staphylococcus aureus. The results varied considerably according to the condition of experiment. With a brush discharge obtained from an Oudin resonator sterilisation was in every case complete after an exposure of from 10 to 20 minutes. With a condenser discharge, obtained from the solenoid portion of the apparatus and so passed through the emulsion as to avoid any sparking, the result was in every case negative as regards sterilisation; indeed, the vegetative growth of the cultures seemed to be in several instances reinforced. These experiments were of a purely preliminary nature and were being continued. So much seemed to depend on the actual tension of the current employed and on the chemical reactions developed at the points of entry of the current.

Dr. Arthur F. Voelcker exhibited the Heart of a man, aged 61 years, which presented an Aneurysmal Protrusion from the Apex of the Left Ventricle measuring two and a half inches by two inches. This had been diagnosed during life but the man refused to come into the hospital. He was brought in dead three days later. In the Transactions of the Pathological Society of London there were a not inconsiderable number of cases of aneurysm of the heart recorded. Of these the greater number occurred in the left side of the heart, and in the ventricles infinitely more commonly than in the auricles. Of those situated in the left ventricle and excluding those in the intra-ventricular septum there were records of 17 cases. Of these, 10 were situated at the base of the heart, six at the apex, and one about the middle of the heart. In Dr. Voelcker's own post-mortem experience he had come across three aneurysms of the heart and all had been situated at the apex, all had occurred in elderly males, and all had been secondary to myo-malacia due to thickening and narrowing of the coronary arteries. In none of the cases had rupture occurred. Aneurysms of the heart appeared to arise in one of three ways—(1) from involvement of the endocardium and myocardium from direct extension or contact from a valvulitis; (2) from gummatous deposits in the heart muscle; and (3) from a myo-malacia due to obstruction to the vascular supply of a portion of the heart muscle, such as arises from thickening and narrowing of the vessel walls or from the presence of a thrombus or embolus within it. Aneurysms arising from the first cause were generally situated at the base or in the septum, while those arising in either of the other two ways might be either basic or apical.

Dr. H. Campbell Thomson read notes of a case in which a Hat-pin was found Embedded in the Heart. The patient was a female, aged 27 years, who had previously suffered from rheumatic fever with pericarditis. She was admitted into Middlesex Hospital on August 19th, 1901, suffering from symptoms of cardiac failure and died on Sept. 27th, 1901. Post-mortem examination showed the heart to be much enlarged (weighing 16 ounces) and the pericardium was universally adherent. There was marked fibroid degeneration of the heart muscle. The portion of a hat-pin—two and a half inches long—was found to be firmly embedded in the wall of the right ventricle immediately below the pulmonary valves; the point of the pin passed through the wall of the aorta just above the valves and projected into its lumen. The point of the pin was covered with blood-clot, some of which was calcified. Although the pin only passed through about half the diameter of the aorta it had evidently at some time or other impinged on the opposite side, as evidenced by a localised injury to the wall of the aorta.

Mr. Leslie Milburn narrated some investigations into an Epidemic simulating Tuberculosis among the laboratory guinea-pigs. It was a nodular disease and the bacillus isolated from these cases was very similar to that obtained by Muir and Klein from the so-called pseudo-tuberculosis occurring amongst birds. Numerous other observers had described bacilli differing but slightly from that isolated by Mr. Milburn. The chief points of difference amongst these various bacilli were seen in the difference of their growth on potato and the varying degree of motility shown by the bacillus when cultivated in broth.

Mr. H. J. Curtis showed some specimens exhibiting the results of Experimental Yeast Infections. The exhibit included a guinea-pig inoculated 18 days previously intraperitoneally with the yeast, saccharomyces neoformans, used by Sanfelice in his famous experiments in 1894, and originally isolated by him from certain fruit juices. The animal was killed by chloroform, but appeared healthy up to the time of death, when numerous cream-white tumours were seen occupying the peritoneum covering certain of the viscera, notably the kidneys and the spleen, which was also itself involved in the disease. Both sides of the diaphragm were greatly affected, being freely sprinkled over with the tiny tumours. The liver and pancreas were not so obviously invaded as in a former specimen. The lungs and pleura were similarly involved in disease. Under the microscope sections of invaded tissues and organs covered by invaded peritoneum were shown and the yeast demonstrated, as also in the case of Klein's yeast isolated from milk and inoculated into the popliteal space of a guinea-pig. The result of injection was to produce an indurated swelling locally, and infection of the superficial and deep inguinal, and the sublumbar glands. There was no involvement of the peritoneum or the abdominal viscera. In the case of both yeasts—one, saccharomyces neoformans, inoculated intra-peritoneally, the other, Klein's yeast, inoculated into the popliteal space—pure cultures were obtained from the heart's blood and these, with pure sub-cultures of the yeast and films prepared from them, were on view. Generally speaking, death resulted in about from two to four weeks' time after either mode of inoculation.

Mr. C. G. Seligmann described some observations made on the fluid withdrawn from two knee-joints in cases of Charcot's Joint Disease associated with Locomotor Ataxy. Both cases yielded a clear orange-yellow, highly viscid fluid with a pronounced alkaline reaction. This fluid completely inhibited the growth of bacteria of the following species: bacillus coli, bacillus typhosus, streptococcus pyogenes, staphylococcus aureus, staphylococcus albus, and staphylococcus citreus. Portions of blood-clot left soaking in the fluid in an open vessel in the laboratory did not become putrid, but fungi grew abundantly on the surface of such a mixture which had dried up. Loops of the fluid in which the above-mentioned bacteria had been placed were transferred to broth at intervals varying from two to 36 days. In every instance growth occurred. The fluid when diluted with 50 per cent. of broth ceased to produce an inhibitory effect. Chemically the fluid did not contain mucin. Microscopically motile coli and typhosus subjected to the action of the fluid were quickly immobilised and to a certain extent clumped. The blood serum of one of the patients had no such effect; that of the other was not tested.

Mr. N. Bishop Harman demonstrated a Method of Ascertaining the Course of the Lesion produced by Bullet Wounds through the Brain. The case demonstrated in this manner was that of a soldier from South Africa shot in the head whilst asleep on the veldt. Measurements of the sites of the shot wounds were made and marked out upon a cadaver whose head measurements coincided with those of the patient. The brain was hardened *in situ* by injection with formalin; the wounds were then produced by trephining and drilling and the brain was removed. In the case in point the symptoms of transient paralysis of the right side, slight speech confusion, and blindness of the right halves of the visual fields, with a persistent weakness of the right arm, homonymous hemianopsia, with an additional complication of the left rim of the left field, were well accounted for by the nature and extent of the brain lesion as demonstrated in this way.

OPHTHALMOLOGICAL SOCIETY.

Exhibition of Cases and Specimens.

A clinical meeting of this society was held on May 1st, Dr. **David Little**, the President, being in the chair.

Mr. H. B. Grimsdale showed a case of Paralysis of the Cervical Sympathetic. There was slight exophthalmos; the pupil was small and reacted very badly. Vision was bare perception of light; tension — 3. Cocaine had no action on the pupil or on the eyelid and there was a grey reflex in the pupil, possibly a detached retina.—Mr. **W. T. Holmes Spicer** thought that a purulent retinitis would explain all the symptoms and he thought that the case was one of those usually called pseudo-glioma.—Mr. **Grimsdale** thought that the failure of the reaction of cocaine proved it to be a paralysis of the sympathetic.

Mr. **Grimsdale** also showed a case of Congenital Unilateral Ptosis in which movements of the eyelid were associated with suction.

Mr. W. ADAMS FROST showed a case of Multiple Ruptures of the Choroid caused by a blow from a buckle of a belt. Some of the lesions seen were more like hæmorrhages than ruptures.—Mr. W. C. ROCKLIFFE had recently seen two similar cases due to a blow with a steel hawser.—Mr. J. H. FISHER said that if some of them were hæmorrhages they were in the choroid and that therefore a rupture of some part of the choroid must have taken place in order to produce them.

Mr. FROST also showed a case of an Unusual Retinal Reflex. The fundus was unusually dark and the patient's father had retinitis pigmentosa. Mr. Frost looked upon this case as physiological.

Mr. TREACHER COLLINS showed a case presenting Unusual *Opacities in the Central Part of each Cornea.* The patient was a carman, aged 33 years, whose sight had been failing for two years. There had never been any real keratitis, but in the central part of each cornea were numerous white radiating lines of opacity; the periphery of the cornea was quite clear. Mr. Collins thought that these opacities were in the anterior layers of the substantia propria and were due to infiltration and degeneration with small calcareous deposits.—Dr. A. BRONNER thought that they were very superficial and might be scraped.—Mr. J. B. LAWFORD had a somewhat similar case in a woman, aged 21 years, who had had recent ulcerative keratitis. This had given rise to a central corneal opacity without injection but with great photophobia. He scraped the cornea and this was now being examined bacteriologically. He suggested that this might be done in the present case.

Mr. L. V. CARGILL showed a case of Corneal Opacity after Instrumental Delivery. The case was a difficult brow presentation in which great force had been used with the forceps. The condition was clearing and only a slight band of opacity now remained across the cornea.

Mr. C. W. THOMPSON showed a case of Obliteration of a Retinal Artery following Attacks of Temporary Amblyopia. The patient was a woman who for the last 10 years had suffered from severe headaches with temporary loss of vision. In September last she had an attack from which the vision had never properly recovered, the dulness she then noticed persisting to some extent. As a rule the vision returned after the attack had passed off. The disc was now partially atrophied.—Mr. LAWFORD thought that this represented a most important class of case seeing how common temporary loss of vision was in association with migraine and how seldom it was that ophthalmoscopic changes were seen in connexion with it. Some of them might be caused by spasm of the vessels which left the artery no less patent than it was before. He had recently had under his care a man, aged 35 years, who habitually overworked himself and who after being much underfed during Lent had developed dimness in the right eye which had persisted. For many years he had had temporary attacks of dimness, but now there was partial obliteration of one of the retinal arteries with hæmorrhages and at other places were seen old changes which apparently indicated lesser lesions of a similar nature in times gone by.—Dr. A. H. THOMPSON asked if it were a case of endarteritis obliterans, as he hardly thought that spasm would last for so long a time.—Dr. JAMES TAYLOR thought that this case was similar to cases of temporary loss of function of some portion of the brain. This sometimes led to permanent changes.—Dr. R. D. BATTEN described a somewhat similar case.—Mr. G. W. ROLL drew a parallel between this condition and Raynaud's disease.—Mr. FISHER thought the tendency of opinion was that arterial degeneration was always present. This he did not consider was the case.—Mr. THOMPSON, in reply, was inclined to the opinion that there was endarteritis present.

Dr. BRONNER showed some sections of a Conjunctival Lipoma in an infant.

Mr. ROCKLIFFE showed a case of very Rapidly Recurring Glioma of the Orbit.

Mr. W. LANG showed a child whose Orbit had been Wounded with a Pitchfork. The ophthalmoscope showed a white patch of exudation where the disc should be and he thought that the optic nerve was torn across close behind the globe.

HUNTERIAN SOCIETY.

Exhibition of Case and Specimens.

A CLINICAL meeting of this society was held on April 23th, Dr. A. L. GALABIN, the President, being in the chair.

Sir HUGH BEEVOR, Bart., showed a case of Probable Complete Atelectasis of the Right Lung from Birth. With regard to the right lung the upper lobe appeared to be represented on the surface of the chest only by a small area against the clavicle. Evidence of fibroid disease, of pleural thickening, or of tumour was wanting and suggested collapse, acquired or congenital. Double coloboma of the iris and sector-shaped opacities of the lens, perhaps also the high and narrow palate, were of congenital origin. These latter deficiencies seemed to render it probable that the case was one of atelectasis from birth. The notes of the case were as follows. A woman, aged 24 years, single, had been three weeks under observation as an in-patient at Victoria Park Hospital. She had sought advice for pain in the chest and this had been alleviated by treatment for dyspepsia. The patient was small and of apparently feeble physique, yet her family history revealed no weakness in the parents or in their children. Her previous history was one of exceptional freedom from even childish ailments, an attack of diarrhœa being all that her mother could recall. A skiagram taken by Dr. Martin showed the heart entirely on the right side. There were no signs suggesting intrinsic disease of the heart but it was displaced extravagantly, the apex or maximum impulse being felt in the right axilla in the third interspace and five and a half inches from the midsternal line. In the first three interspaces pulsation might be seen and felt, it was also just palpable under the left breast. Dulness extended from the right margin of the sternum to the mid-axilla and from the third interspace downward; above this interspace was a less degree of dulness, specially less over the inner portion of the first two spaces and above the clavicle. Percussion elsewhere showed an impaired note only on the right side behind from the middle of the scapula upward and to the axilla. Cardiac auscultation revealed a faint systolic murmur best heard at the base, a common symptom in right-sided displacement. Pulmonary auscultation showed a very faint respiratory murmur above the abnormal cardiac dulness without evidence of consolidation with patent bronchi. Vocal fremitus was equal above the clavicles and was absent below the right. There was no clubbing of the fingers. The other organs were found to be normal.

Mr. JOHN ADAMS showed a specimen of Congenitally Diseased Heart displaying extreme deformity. The patient from whom the specimen described was taken was a woman, aged 23 years; she was shown at a meeting of this society on April 13th, 1898, when many of the following facts relating to her physical condition were commented on. She was of average height, the face and hands were plum-coloured, and there was clubbing of the fingers. As a rule she could do light work; dyspnœa was only present on exertion. She was always able to sleep in a recumbent position and there was no œdema till a few days before her death. She was liable to severe attacks of bronchitis, in which she would become livid and semi-comatose. Death resulted from cardiac failure consequent on a bronchitic attack. Physical examination during life showed an enormously enlarged area of cardiac dulness, six inches in transverse diameter, extending from the apex beat, which was in the fifth interspace an inch external to the nipple line. A loud systolic murmur could be heard all over the front of the chest, less clearly behind; it was most pronounced over the pulmonary area. The heart showed gross congenital defects. The organ was much broader than natural, measuring about four and a half inches from side to side; indeed, its breadth exceeded its height. It was roughly wedge-shaped instead of conical, and terminated below in a ridge which belonged as much to one ventricle as to the other. The two ventricles were nearly equal in size and in the thickness of their walls, but internally the left ventricle had a greater vertical extent than the right, which it thus exceeded in capacity. The size of the right auricle, on the contrary, exceeded that of the left at least threefold and the enormously dilated coronary sinus extended between the left auricle and the base of the left ventricle. The left appendix auriculæ was comparatively small. The foramen ovale was widely patent so as to throw the cavities of the two auricles into one; the septum was practically absent. The inter-ventricular septum was also widely incomplete at its upper part, so that two fingers could be passed from one ventricle into the other. The mitral and tricuspid valves were thickened and the orifices were narrowed, especially that of the tricuspid, which would admit two fingers. Seen from below the curtains of both valves showed some coherence; in addition to this recent vegetations were present in both. The aorta sprang from a wide orifice above the gap in the inter-ventricular septum, springing equally from both ventricles. It had the usual three sigmoid valves. Though of more than normal size at its origin it soon diminished and the arch was much smaller than usual, while the descending aorta showed an even more marked narrowing. The carotid and subclavian trunks arose separately and irregularly from the arch and could not be identified with accuracy. The pulmonary artery arose by a small orifice from the right ventricle immediately in front of the gap in the septum. Only two sigmoid valves were present and these were much thickened and coherent, projecting up into the lumen of the vessel as a dome with the aperture at its apex which just admitted a common penholder. The cavity of the pulmonary artery itself was not much reduced in capacity and it was distributed normally to the two lungs. There was no persistent ductus arteriosus. The chief abnormalities were as follows: (1) patent foramen ovale, (2) perforate septum ventriculi, (3) pulmonary stenosis, (4) *mitral stenosis*, (5) tricuspid stenosis, (6) aorta arising from both ventricles, (7) branches of the aorta irregular, and (8) dilated coronary sinus.

Dr. W. MILLIGAN showed a specimen of Cerebral Tumour. The clinical interest of the case lay in the fact that the following symptoms had been absent: (1) vomiting, (2) optic neuritis, (3) slow pulse, and (4) definite localising symptoms. The course had been variable and the symptoms had yielded partially to iodide of potassium. The necropsy showed a large tumour in the posterior part of the right parietal lobe. The tumour was adherent to the membranes and its central part was necrotic. The vessels had hyaline coats from lardaceous disease. In some parts there was well-marked periarteritis.

The following took part in the discussion of the cases and specimens: Dr. T. H. ARNOLD CHAPLIN, Mr. JOHN ADAMS, Sir HUGH BEEVOR, Bart., Dr. R. HINGSTON FOX, Mr. F. R. HUMPHREYS, Dr. MILLIGAN, Mr. J. H. TARGETT, and the PRESIDENT.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Carcinoma of the Pylorus.—Food Preservatives.—Annual Meeting.

A MEETING of this society was held on May 2nd, Dr. A. G. BARRS, the President, being in the chair.

Mr. G. P. ANNING related a case of Carcinoma of the Pylorus in a youth, aged 19 years. The earliest symptoms were vomiting and emaciation and later marked anæmia. Eight months after the commencement of the illness the patient came under the care of Mr. Anning. The pylorus could not be palpated but the coronary glands arranged along the greater curvature could be felt. There were now frequent vomiting and severe pain. The diagnosis lay between pyloric stenosis with simple enlargement of the glands, malignant disease of the stomach, and tuberculosis.—Mr. H. LITTLEWOOD performed posterior gastro-enterostomy after which the symptoms of gastric disease disappeared. Secondary growths, however, soon appeared in the liver and the patient died. The growth was proved to be a scirrhous carcinoma.—Mr. MAYO ROBSON, Mr. H. LITTLEWOOD, Dr. J. E. EDDISON, Mr. P. J. CAMMIDGE, and the PRESIDENT took part in the discussion and Mr. ANNING replied.

Dr. A. E. PORTER read a paper on Food Preservatives, pointing out that nearly every article of food and drink which was liable to fermentative changes might be adulterated by the addition of boron compounds, salicylic acid, formic aldehyde, sulphites, or similar antiseptics. Dealing chiefly with the boron compounds he showed that this class of preservative was unlikely, in the proportion usually found in foods, to exert a prejudicial effect on the digestive ferments, with the possible exception of rennin and amylopsin in the cases of borax and boric acid respectively, though meat which had been exposed to a mixture of these antiseptics was less readily digested by gastric juice. It was further mentioned that feeding experiments on animals had usually given negative results, though Dr. H. E. Annott's observations on newly-born kittens suggested that in the very young nutrition might be impaired. No such result was, however, noted in the case of three children between the ages of two and a half and five years to whom boric acid and borax were given in quantities exceeding the relative medicinal doses. It appeared, nevertheless, that a considerable proportion of the population were liable to manifest toxic symptoms on account either of idiosyncrasy or deficient excretory powers, and to suffer from vomiting, diarrhœa, and skin eruptions of some severity, upon the administration of medicinal doses of boric acid. The largest daily doses would probably be taken in milk and the result in the case of a patient suffering from Bright's disease or gastro-enteritis therefore might be disastrous. Milk had been found to contain as much as 80 grains of boric acid per pint, probably on account of the opportunities which existed for the successive addition of the antiseptic at different stages of the milk traffic, a practice fostered by the misleading advertisements on some of the patent trade preparations. Amongst other common articles of diet by means of which boron compounds might be unknowingly introduced were mentioned cream, butter, margarine, ham, bacon, sausages, and pork pies. As there should not be the slightest necessity for such an addition in the majority of foods it was considered that the public were exposed to an unnecessary risk. Dr. Porter regretted that no effective legislation existed enabling local authorities to check a practice by which the public were liable to the indiscriminate administration of powerful drugs which should only be taken under medical supervision.

The PRESIDENT, Mr. CAMMIDGE, and Dr. EDDISON discussed the paper and Dr. PORTER replied.

The annual meeting was held at the close of the ordinary meeting. The report showed the society to be in a flourishing condition, the membership being over 350 and the average attendance nearly 60.

On a motion to admit lady practitioners to the membership of the society it was decided to obtain by circular the opinion of the members of the society before proceeding further.

The following officers were elected for the next session: President: Dr. John Irving (Huddersfield). Vice-Presidents: Mr. C. Richardson and Dr. A. Bronner (Bradford). Committee: Mr. C. J. Wright, Dr. F. W. Robinson (Huddersfield), Dr. J. Gordon Sharp, Dr. D. Sanderson Long (York), Dr. Priestley Leech (Halifax), Dr. J. Gordon Black (Harrogate), Mr. Edwin Roberts, Dr. A. H. Bampton (Ilkley), Mr. Walter Thompson, Dr. J. W. H. Brown, Mr. J. G. E. Colby (Malton), Mr. S. M. Hebblethwaite (Harewood), Mr. C. Powell White, and Mr. J. H. Woods (Batley). Treasurer: Dr. J. E. Eddison. Librarian: Dr. A. G. Barrs. Auditor: Dr. C. M. Chadwick. Honorary Secretaries: Dr. E. F. Trevelyan and Mr. R. Lawford Knaggs.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

The Rotunda Hospital Report for 1901.

A MEETING of this section was held on April 18th, Dr. W. J. SMYLY, the President, being in the chair.

Dr. R. D. PUREFOY, Master of the Rotunda Hospital, proposed a vote of condolence and sympathy with the family of the late Dr. Thomas More Madden, a foundation Fellow of the Academy and for many years one of its most regular attendants. His contributions to the Obstetrical Section were numerous and valuable and his pathological exhibits were among the most interesting.—Dr. GEORGE M. FOY having seconded the motion it was passed in silence.

Dr. A. V. MACAN then opened the discussion on the Rotunda Hospital Report for 1901 and congratulated Dr. Purefoy on the satisfactory nature of the report, although there were a few points in it which he thought called for observation. In Table III. he found that in 286 cases of abortion curetting was thought necessary 200 times, which was a very large proportion—two out of three cases. Curetting was attended with danger in the puerperium; he had seen the principal assistant in a South German clinic perforate the uterus at the very beginning of the operation. The application of the forceps in the extern maternity had the low proportion of 1 in 57·2 cases. Personal considerations entered so largely into the greater or less proportion of cases in which they should be used that not much could be said on the question, but he could not understand why it was necessary to have such a high proportion as one forceps delivery in 24·5 of the cases in the hospital, where the patient was throughout under observation and the forceps could, if necessary, be applied at any

Pp. 216. Price 1s.—The purport of this book is explained by the sub-title which is as follows: "A Year-book of Scholarships and Examinations at Schools, Colleges, and Universities for the Year 1902." The scholarships and prizes of the various county councils and of the London School Board are also included. The publication will be found useful by parents and guardians in deciding for what aids to education in the form of scholarships or prizes those for whom they are responsible shall apply.

Transactions of the American Ophthalmological Society, Thirty-seventh Annual Meeting, New London, Connecticut, 1901. Hartford: Published by the Society. 8vo, pp. 405 Press of the Case, Lockwood, and Brainard Company.—The present number of these Transactions contains much interesting material for study and the cases reported are, in many instances illustrated by excellent drawings, chromo-lithographs, and photographs. As there are 30 articles besides a report of a committee on standards and methods for examination in respect to acuteness of vision, colour sense, and hearing, of which Dr. C. H. Williams was chairman, it is impossible to mention any but those that seem to possess special interest. There is a valuable report at the commencement of the volume giving supplementary histories of numerous cases that have been recorded in the Transactions of the American Ophthalmological Society prior to 1900. Dr. Wilbur B. Marple of New York City contributes an article on the Pathology of Vascular Growths into the Vitreous, illustrated with several plates showing the conditions in an interesting case under the author's care. In this case the retina was detached and the appearances were so threatening that enucleation was advised and practised. Dr. Marple has collected the history of several other cases. A case of Melanotic Giant Cell Sarcoma of the Limbus Corneæ associated with an Implanted Secondary Growth in the Lower Eyelid is described and illustrated by Oliver F. Wadsworth, M.D., of Boston, Mass., and Frederick H. Verhoeff, M.D., also of Boston, Mass. A histological description of an Eyeball with Dropsical Degeneration of the Rods and Cones of the Retina Simulating Glioma is given, with illustrations by G. E. de Schweinitz, M.D., and E. A. Schumway, M.D., both of Philadelphia, Penn. Another article, by Dr. G. E. de Schweinitz, is on the Treatment of the Apparently Unaffected, or at most but slightly Implicated, Eye in cases of Monolateral Glaucoma. Dr. de Schweinitz recommends the employment of a myotic and then iridectomy. Charles S. Bull, M.D., of New York, describes a series of Six Cases of Metastatic Choroiditis occurring in the course of Pneumonia due to Grippe; in two of the cases necropsies were performed. Several interesting cases of the Entrance of Foreign Bodies into the Eye are recorded by S. B. St. John, M.D., of Hartford, Conn., who gives an excellent photograph showing the position of the piece of steel; by Alvin A. Hubbell, M.D., of Buffalo, N.Y., in whose case the foreign body remained for nearly 18 years, setting up several attacks of sympathetic irritation which were successively subdued; it was ultimately removed without complete loss of vision in the injured eye and with perfect recovery of vision in the sympathising eye; and by William M. Sweet, M.D., of Philadelphia, Penn., who particularly dwells on the diagnosis of foreign bodies in the eye. A variety of new instruments are described by Carl Koller, M.D., of New York City, who has devised a Corneal Loupe; by Charles H. Williams, M.D., Boston, Mass., who gives a drawing of an Incandescent Lamp for Ophthalmoscopic Examination; by William Thomson, M.D., and Archibald G. Thomson, M.D., of Philadelphia, Penn., who have invented an Improved Means for detecting Colour-blindness; and by Samuel Theobald, M.D., of Baltimore, Ind., who suggests a New Instrument for Preventing Incarceration of the Iris in Iridectomy Operations.

JOURNALS AND MAGAZINES.

Revue d'Hygiène et de Police Sanitaire. Vol. XXIV., No. 2. February, 1902. Paris: Masson et Cie.—This number contains the text of the new French law for the protection of the public health which was adopted by the Senate on Feb. 4th and which will come into operation one year after its promulgation. In the next number we are promised a discussion of the measure. Dr. Vaillard completes his series of articles on Preserved Meats, the accidents which they provoke, their cause, and the means of preventing them. Among the necessary precautions the author insists upon the inspection of animals whose flesh is intended for use as preserved meats, cleanliness during the process of preparation, and the rigorous sterilisation of the meat. Dr. le Roy des Barres gives an interesting account of Five Epidemics of Diphtheria at Saint Denis, the first of which is supposed to have occurred as far back as 1827, and the last took place in 1901. In this latter outbreak the excellent effects of antitoxin were very apparent. Among other papers is an exhaustive one by Dr. Ch. Doptes on Disinfection by Spraying with a Solution of Formol, and a contribution from Mr. M. H. Emery on a Method of Differentiating the Enteric Fever Bacillus from the Bacillus Coli.

Public Health. No. 6, vol. XIV. London: Rebman, Limited.—One of the editorial articles in this number discusses the somewhat difficult question of the relationship of the public vaccinator and the medical officer of health to the general practitioner. The editor thinks that every general practitioner should be the recipient of Government lymph and that he should also act as a local public vaccinator. The other editorial article deplores the unfortunate *impasse* which has taken place at Glasgow, and surely it might be added in certain large towns in England, in consequence of the sanitary inspector occupying a position which enables him to act independently of the medical officer of health. Other articles comprise papers on Plague and its Prevention, by Dr. D. S. Davies, Dr. E. W. Hope, and others, and an interesting study by Dr. W. H. Symons on the Distribution of Phthisis.

The Cornhill Magazine—The number for April is full of good things. The paper which appeals most to us in our capacity of medical journalists is the "Londoner's Log-book," wherein the "Londoner" gracefully banters the self-styled Christian Scientists. We quote the passage: "Great was my consternation when the other day I found added to the collection a pamphlet entitled 'The Wonders of Thought-Force.' The title startled me. Since she was vaccinated Selina has lost all fear of small-pox, declares that she was a goose for giving way to Dr. Snuffin's nonsense, and affirms her belief that, if people would only set to work in the right way, they could be perfectly healthy without any doctors' abominations. True it is that Grape-nuts have proved a failure and the Salisbury Treatment has palled; but I am not free from apprehension that she is turning her mind in directions even less compatible with orthodoxy. This I trace to the influence of young Lady Farringford (*née* Sally Van Oof), who, I feel certain, has given her the pamphlet on 'Thought-Force,' setting forth the miraculous cures of physical and mental ailments effected by Helen Wilmans Post, Sea Breeze, Florida, U.S.A. From that pamphlet I cull two or three quotations—'racy,' as Pennialinus would say of the Great Republic—and of that 'high faith' which Mr. Lowell commended. 'John M. White, North Wales, Pa., S.S.—Mrs. Wilmans Post,—I most cheerfully give you my testimonial of the great good you have done me by your absent treatment. Five years ago I was a physical wreck beyond the reach of the best medical doctors, as five years of experience proved. I went to the best doctors to be found here and in Philadelphia, and as a last resort I went oment considered advisable. In his own practice he now ldom applied the forceps and he thought that the less ey were used the better. Table V. (cases of contracted lvis) recorded the case of a woman with an antero-sterior measurement of 7 5 centimetres who, unaided, gave rth to a living child eight and a half pounds in weight. his case was remarkable, for the measurement was below at which was considered necessary for the birth of a ving child. In the treatment of accidental hæmorrhage e observed that the oxytocic properties of quinine were elieved in. As for himself he had never found evidences the alkaloid possessing such properties, and he thought at five grains of it would not have much effect. The case Cæsarean section was rather obscurely reported. "Large broid lifted out of pelvis; pedicle transfixed and tied." as it the pedicle of the tumour or of the uterus? If of the atter the operation performed was that of Porro.

Dr. H. JELLETT congratulated Dr. Purefoy on his nteresting report. There were just a few points left for riticism. He thought as he read it over that somebody had orked very hard at it for 24 hours in collecting a great mass materials and then had neglected to spend a couple of ours in putting them into shape. In the case of rupture of he uterus and vagina he considered that the accident was ue to the plugging, the tampon being allowed to remain fter the uterine contraction had commenced. He considered hat the tampon should be removed when the uterine pains ere well begun. Quite recently a student of the Rotunda ospital told him that the plug was allowed to remain n position until expelled with the child. He could not elp thinking that the measurements given in the table eaded "Contracted Pelvis" must be wrongly taken. enstruation appeared to him to be a misnomer for the red ischarge that occurred in newly-born female children. It as an isolated hæmorrhage, not a menstrual flow.

The PRESIDENT congratulated Dr. Purefoy on his excellent eport and on the very low mortality of three out of 1600 ases. While he (the President) was Master of the Rotunda ospital ophthalmia neonatorum was one of the troubles hich he prided himself on keeping the house clear of and et on one occasion when some ophthalmic surgeons were resent in the section now sitting he heard that their hospital linics were crowded with cases of disease in the children who came from the Rotunda Hospital.

Dr. PUREFOY said that he thanked the members of the ection for the reception which they had given to his report, articularly those who had pointed out its defects. Dr. Macan had waxed eloquent on the unwisdom of curetting, but he did not agree with him at all. He had had a very large experience both in the Coombe and in the Rotunda hospitals, and he was of opinion that the sooner the accoucheur curetted and removed all septic matter from the womb the better. Forceps were used under the indications plainly pointed out. He acted according to the nature of the case and the condition of the patient. The oxytocic properties of quinine were known and advantage was taken of them to stimulate uterine action. He found that five-grain doses of the alkaloid every four or six hours were an excellent oxytocic remedy. The success of the prophylactic treatment of ophthalmia neonatorum was shown by the fact that they had only four cases among more than 1600 children. They used from one to three drops of a 2 per cent. solution of nitrate of silver. As for the objection to the term "menstruation" it was futile; for all he (Dr. Purefoy) knew the child might have menstruated at the next monthly period

---

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 15th, Mr. Philip E. Miall being in the chair.—Dr. F. W. Eurich gave a Microscopical Demonstration.—Dr. A. Bronner showed (1) cases of Extraction of Senile Cataract without Iridectomy; and (2) a patient whose Nose had been Improved in Appearance by the Subcutaneous Injection of Paraffin.—Dr. C. F. M. Althorp showed a skiagram of a Fractured Ulna with dislocation inwards of the head of the radius.—Dr. T. Jason Wood showed (1) a Meckel's Diverticulum of the Ileum removed by operation from a child who had had a discharging sinus at the umbilicus since birth, and (2) a Gangrenous Appendix Vermiformis from a case of general peritonitis.—Mr. W. H. Horrocks read a paper on the Remains of the Hymen. He pointed out that in a certain number of women the tags of the hymen, instead of being insensitive, became acutely inflamed and tender. The inflammation was perpetuated by marital intercourse and by any discharge or moisture there might be about the parts. Great pain was caused when the parts were touched and when the patient walked about smarting was set up. A state of spasm might be induced which was called by Marion Sims "vaginismus." The treatment for the condition was free stretching of the vaginal orifice together with removal of the inflamed tags of the hymen. This was usually quite successful in relieving the symptoms. A number of cases were detailed which had been cured by the treatment advocated.—Dr. Althorp read notes on a case of Hydatidiform Mole which had been expelled after dilatation and packing of the uterine cavity with gauze.—Mr. E. Prothoroe Smith read notes on a case of Chronic Inversion of the Uterus. The patient was admitted to the Bradford Royal Infirmary in January, 1902, complaining of menorrhagia and metrorrhagia. She was 24 years of age and was married. She had had good health with regular menstruation till her first and only pregnancy in 1899 She was delivered of a child in November of that year. She stated that she had lost a good deal of blood after the birth of the child, but she did not know much about it as she was under chloroform at the time. Three weeks after the confinement, nothing unusual having previously occurred, the "womb came down" and she had to press it back. The same thing had happened five or six times since. Menstruation had occurred every three weeks since the confinement and had been excessive. There was no pain except on sexual intercourse. In November, 1901, she began to have frequent floodings. An anæsthetic was administered and an inversion of the uterus was discovered which it was not found possible to reduce by manipulation. On admission the patient was pale and she complained of constantly losing blood per vaginam. Examination by the vagina showed a smooth rounded tumour projecting through the os uteri which bled readily when touched but was not tender The finger and sound could be passed through the external os to the base of the tumour but could not be passed beyond the cervix. Rectal examination showed that the body of the uterus was not in its usual position. A dimple could be felt on the top of the tumour. Galabin's modification of Aveling's repositor was applied on Jan. 26th at 1 P.M. The patient complained of pain nearly all the time that it was in position and twice during the following day she said that she felt something slip in her inside. The repositor was removed at 8 P.M. on the 27th. The tumour was found to have disappeared from the vagina. The os was dilated and a finger passed through it felt no tumour but a rough surface on the left side of the internal os. The body of the uterus was felt in the normal position. The temperature rose to 101·2° F. in the next three days and it then fell steadily. On Feb. 8th some offensive discharge was followed by a cast of the uterine cavity. She left the hospital on March 4th, the cervix uteri still being rather softer than normal.

ROCHDALE AND DISTRICT MEDICAL SOCIETY.—A meeting of this society was held on May 1st.—Mr. S. Lord showed a case of Nervous Disease. The patient, a woman, aged 37 years, had suffered from tuberculous adenitis and ulceration of the face. The present illness began in October last and was characterised by ataxia of the lower limbs with exaggerated reflexes and no loss of power. About December there had been girdle pain lasting two months and incontinence of urine lasting six weeks. There was no tender spot over the spine. The case was probably one of tuberculous pachymeningitis of the cord in the course of which there had been a localised acute attack of myelitis.—Mr. W. Atkin Thompson had seen a similar case in which the necropsy revealed caries of the body of one vertebra.—Dr. W. J. Kerr showed the Kidneys from a boy, aged one year and ten months. Both were enlarged and cystic, the left extremely so. There had been no noticeable abnormality in the quantity of urine during life. Respiratory movements had been much embarrassed by the size of the left kidney.—Dr. Kerr also read notes of a case of extensive Diabetic Gangrene in a girl, aged two and a half years. The child was not known to be ill when the gangrene appeared in the left leg in the course of the night and in the morning extended from the foot to the knee. The right foot and hip became affected the following day. The temperature rose to 107° F. just before death —Mr Thompson read notes of three cases: (1) Ludwig's Angina treated by free incision with good recovery; (2) Sublingual Abscess; and (3) Surgical

Emphysema as a complication of Measles and extending from the neck over the chest and abdominal walls.

GLASGOW SOUTHERN MEDICAL SOCIETY.—A meeting of this society was held on May 1st, Dr. John Stewart, the President, being in the chair.—Dr. Carstairs C. Douglas read a paper entitled "Life Assurance Examination and the Relation of the Medical Examiner to the Company." In introducing his subject Dr. Douglas made reference to the different kinds of life assurance companies at present in existence and gave a description of the method by which such important businesses were conducted. Speaking with special reference to the relationship of the medical examiner of the company to the person about to be assured he remarked that any statements made during the examination were presumably confidential and no action for damages could legitimately be brought against the medical practitioner. Dr. Douglas then referred to the want of proper remuneration of medical examiners by assurance companies, citing during his review some glaring examples of the kind. Important points in the course of the examination itself were next alluded to, the speaker dealing first in a general way with the different systems of the body. The different organs were then in turn reviewed, and lastly was discussed the importance to be attached to the presence of syphilis, glycosuria, and albuminuria.—The paper was favourably criticised by many members and on the motion of the President Dr. Douglas received the thanks of the society.

Reviews and Notices of Books.

The Motor Car, its Nature, Use, and Management. By Sir HENRY THOMPSON, Bart., F.R.C.S. Eng. London: Frederick Warne and Co. 1902. Small crown 8vo. Price 2*s.* 6*d.*

Motors and Motor Driving. By Various Writers. London: Longmans, Green, and Co. 1902. Crown 8vo, pp. 456. Price 9*s.*

CONSIDERATION of these two volumes may well be taken together and in the columns of THE LANCET the works may be considered mainly from the point of view of the medical practitioner and as dealing with an alternative to the horse-drawn vehicles of everyday practice. To take Sir Henry Thompson's little volume first. In the course of some 80 pages, he deals clearly and with much judgment with motor cars driven (1) by petrol vapour, or rather by its admixture with atmospheric air, fired either by electric spark or ignition tube; (2) by steam; and (3) by electricity. Equally important are the papers, mainly letters reproduced from the *Times*, on the duty of the motor car driver to the public and to the drivers of horses. If all motor car drivers would take to heart Sir Henry Thompson's well-chosen words on this matter there would be less unreasonable prejudice raised against their vehicles. But with his contention that drivers of horses are often more to blame for accidents than are either the horses themselves or the motor cars we are compelled to agree. Sir Henry Thompson very truly observes that the worst possible preparation for an encounter with a motor car is to begin to pull the reins tightly and to lash the horse with the whip. Yet that is what we often see done. Sir Henry Thompson's plan on meeting a horse which shows symptoms of terror is to stop his engine and to beg of the driver of the horse to allow him "to lead the animal quietly up to the motor, so that he may look at it quietly, and then perchance give him a mouthful of fresh grass from the roadside." This is unquestionably the way best calculated to allay the hostility both of the horse and of its driver. Sir Henry Thompson tells us that "he had passed his eightieth year before he gained his first experience of a motor-car drive, and trusts, though a late beginner, he may yet live a year or two longer to enjoy the same pleasure and profit which he has already derived from the practice" hope that will receive the cordial endorsement of all hers of his profession.

The book contains clear illustrations of the working part of a Daimler engine and of the gear box, showing the working of the change speed and differential gears. An appendix contains a list of upwards of 20 routes out of London with mileage. White blank sheets for notes are inserted at the end. Altogether it is a useful little book for the would-be "motorist."

A much larger and more comprehensive work is the volume of the well-known "Badminton Library" which may be said fairly to cover the field and to be an up-to-date review of the subject. With this book before him and the catalogue of the recent exhibition, or the advertisement pages of the *Autocar* or the *Motor Car Journal*, the practitioner should have not much difficulty in deciding which particular car will best meet his requirements, though on this point we would gladly have welcomed a chapter on the question of cost. As in the case of the stable and the saddle room, the amount spent upon the motor car will largely depend upon the individual. One man will always keep one horse, or perhaps two or more horses, more than may be really necessary to do his work and will make a point of hunting one or two days a week through the season, the horses taking their turns at work and sport; another will keep only what he finds actually necessary for professional work and will to all intents and purposes use his horses for nothing else. One man will keep two horses and a dog-cart with a groom-gardener; another will keep a brougham and pair with a coachman and a helper. It is obvious that their saddle and harness-room expenses will differ widely, entirely apart from the mere question of oats and hay. So with the motor car, while one man will be content with a three and a half horse-power car with a boy to oil and to grease it, another may be satisfied with nothing less than a 12 or 16 horse-power car with an expert *mécanicien* and will be regardless of expense in the matter of 90 millimetre pneumatic tyres. On the whole it may be said that the initial outlay on a motor car or on motor cars—for many will prefer to have two and thus to run less risk of being stranded—will be larger than on a reasonably priced horse or two and a dog-cart and that the economy in annual expenditure will be problematical and will depend largely on the question of pneumatic tyres or solids. The motor car from different points of view is dealt with by experts and may—nay, should—be studied for guidance by an intending purchaser. We may particularise the chapters on the Utility of Motor Vehicles, by the Hon. John Scott Montagu; the Choice of a Motor, by Mr. Alfred C. Harmsworth; the Motor Stable and its Management, by Sir David Salomons; the Petrol Engine, by Mr. R. J. Mecredy (editor of the *Motor News*); Ignition, by Mr. Hutton; the Caprices of the Petrol Motor, by the Hon. Chas. Rolls; Tyres, by Mr. C. I. Freeston; Motor Driving, by Messrs. Edge and Jarrott; a useful chapter on Some Points of Law, by the Chairman of the Automobile Club, Mr. Roger Wallace, K.C.; and a useful Glossary in the Appendix.

Possibly the most important section to readers of THE LANCET is that dealing with the "choice of a motor"; and Mr. Harmsworth commences by saying that "of the three or four hundred types and varieties now in existence, many are of no practical use, some are extremely complicated, not a few dangerous, and many more or less faulty in construction"—a premiss to start from with which we entirely agree. Nothing could be more utterly useless to the country practitioner than a small under-powered car not capable of dealing with the hills in his neighbourhood. Those that are too complicated may be ruled out of court at once, even if the buyer resides quite near the manufactory. Amidst the "dangerous" we should certainly be inclined to class for professional, daily, and possibly rough, use, all cars depending on tube ignition, though perhaps it may be passed as a *dernier ressort* in the event of the accumulator giving out. We would recommend the purchase of no car in which really heavy (relative) weights have to be carried and the "drive" borne by balls such as ordinarily are used in bicycle construction; and until vast improvements in their manufacture have been made we cannot—and we speak from personal experience—advise any practitioner to purchase any car running on pneumatic tyres. The annoyance and delay of a "puncture" are hardly to be regarded with equanimity. No matter how seldom it may occur, when it *does* occur it will upset the day's work and cause endless worry, confusion, and expense, for it will probably mean hurried hiring, getting on as fast and as best one can, and telegraphing to the nearest motor works or cycle agents to send out to repair the tyre. Furthermore, the use of pneumatic tyres entirely prohibits the independence which is one of the charms of the motor. To be alone on a lonely road with a collapsed tyre on a heavy car with night coming on, and perhaps in bad weather, is an experience which makes the unhappy owner think a motor car not worth having The frequency of punctures may be judged by the fact that at the "reliability" trials at Glasgow last year it was decided that stops for punctured tyres should "not count," though the original intention was an "absolute non-stop" trial and deductions of marks made for every stop. This may be taken as an *ex cathedrâ* announcement of the Automobile Club of Great Britain and Ireland that punctures are inevitable and "do not count." We may be thought to labour this point, but it is about the most important that the medical practitioner has to consider in the purchase of a car. Perhaps the "New York," or some similar tyre may obviate the difficulty. The ordinary pneumatic tyre with the ordinary outer cover is anathema. With reference to the question of petrol, electricity, or steam, Mr. Harmsworth gives it as his opinion that "a good petrol engine is infinitely the best for all-round work," a view with which we are in accordance. The electric car can obviously only be of use in localities which have facilities for prompt re-charging, while our experience of steam cars is that, though very pleasant vehicles by daylight and while all goes well, they require too much watching and are rather too delicate for use after dark. Those that require a hot "torch" as a preliminary to starting we can hardly recommend for the everyday work of medical practice, and those that are not entirely trustworthy in a high wind must be ruled out of court for the same reason, and perhaps also on the ground of safety.

We have left ourselves but little space for the consideration of other sections, but the chapter on "Caprices" may be studied with advantage by the novice. The advice as to dress, both in Sir Henry Thompson's book and in the Badminton volume, should be carefully studied. Clothing differing from that worn for driving or riding or, in fact, for any other form of travelling is required, and it may be remarked parenthetically that the "motorist" will find his tailor's, draper's, and laundress's bills increased A motor car cannot be touched without gathering grease.

A word must be said for the illustrations The technical ones convey their meaning clearly and if the would-be "motorist" should take alarm at the possibilities of "side slip" we can assure him that incautious driving on a suitable road may produce quite as embarrassing a situation. If the illustration inculcates caution it will not be in vain. In this connexion we are bound to say a word for Wilkinson's tyres. We found a "Century Tandem" very prone to "side slip" on ordinary tyres but since being fitted with Wilkinson's this tendency seems to have disappeared even on very "greasy" roads Even "solids" will skid if the car is permitted "to coast" down hill on a greasy surface but we have not found them to do so unless the car be permitted "to run free."

To sum up, we can strongly recommend the study of these books to any practitioner contemplating the purchase of a motor car.

A Monograph of Culicidæ or Mosquitoes. Mainly compiled from the collections received at the British Museum from various parts of the world in connexion with the investigation into the cause of malaria conducted by the Colonial Office and the Royal Society. By F V. THEOBALD, M.A., F.E.S. London: Printed by order of the Trustees. 1901. Three vols. Vol i., pp. xviii. + 424; vol. ii., pp. viii + 39; and vol. iii., pp. xxxvii. + five plates. Price £3 3s

IN these days of scattered and abundant zoological publications it is of the greatest possible importance to unite into one work what is known of each particular group, a procedure which saves infinite labour for those who are to come after. Inasmuch as Mr. Theobald quotes no less than 13 fairly closely-printed pages full of references to the literature of this, comparatively speaking, minute subdivision of the diptera it is plain that his work has not been undertaken before it was needed. Further than this, the group with which he deals has at the present moment the greatest possible interest in connexion with recent discovery concerning malaria, of which certain species of gnats are the bearers and the sources of infection in human beings. The trustees of the British Museum are therefore to be congratulated on their especially well-timed liberality. The monograph could not have appeared at a more propitious moment. That it is not complete is obviously a foregone conclusion. These insects of small size and absolute ubiquity are most varied in details of organisation; the species, in fact, are quite multitudinous, and it will be long probably before the collections in the Natural History Museum and the descriptions of the same are in a state approaching completion. Indeed, since the appearance of this large monograph, recent though that appearance is, at least one paper, and that a lengthy one, has added a number of new species to those previously known.[1]

The chief aim of the monograph, which is the work of an author already well known as an authority upon the diptera, or two-winged flies, is zoological; the preponderant bulk of the work is devoted to the explanation of the structure of these flies and to the systematic arrangement and the definition of genera and species of the same. It will thus be of great advantage (to quote Professor Lankester's editorial preface) "to enable the medical men engaged in tracing the connexion between mosquitoes and human disease to identify and speak with precision of the species implicated." There is, however, a short and valuable *résumé* of the rôle which these insects play in the dissemination of disease. Probably the public at large connect the culicidæ with the conveyance of malaria only But these insects are intimately connected with the transference of yellow fever and filariasis, and there are grounds for suspecting them to be prime movers in the distribution of other complaints. It is, however, clear that a given mosquito is not necessarily dangerous as a possible carrier of disease. To the non-expert the difference between the genus anopheles and the closely allied culex is not great and even to the better informed not always patent But while the anopheles has been conclusively proved to be the pest which not only carries but helps in engendering malaria, the culex is quite guiltless and its bites may be received with impunity so far as the more deadly consequences of such bites are concerned. Investigations by Major Ronald Ross, late I M.S, have shown that the parasite, a protozoön which is directly related to malaria will not live in the body of the culex, or rather that it will not undergo development therein. Hence a monograph setting forth plainly, as does Mr Theobald's monograph, the anatomical differences which distinguish these two genera is necessary to the practitioner as a manual. But more than this, it is not certain that all species even of the deadly anopheles can act as germ-carriers. It is therefore of the highest importance to state which species have been ascertained to nourish the parasite in malaria-haunted districts. But the two genera just mentioned by no means exhaust the generic types into which the culicidæ may be divided. Mr. Theobald allows no less than 20 other genera, but less appears to be known of their import as disease-bearers. One, and perhaps the most singular, feature about these biting flies is that their natural food would appear to be the juices of plants. The transition from piercing and sucking the tender shoot of a plant to treating in the same fashion the skin of a human being is from one point of view not great, though the difference in the nature of the food would seem to preclude such a change of habit. Furthermore, it has been estimated, or, indeed, according to some, under-estimated, that not one mosquito in a million ever gets a taste of human blood. How do the millions flourish that have not the opportunity of this more stimulating diet? The problem is hard to solve. It is more easy to grasp the meaning of the fact that with rare exceptions it is the female insect only which sucks blood. The female needs more nutriment than the male for the development of her large and yelk-laden eggs. There is, however, at least one species, the *Stegomyia fasciata*, referred to by Mr. Theobald in which the male is as carnivorous as the female. But according to one authority quoted by the author the male mosquito varies his vegetable diet when he can with wine. "Male mosquitoes are fond of wine," writes this gentleman, "and every evening at dinner I see some on the stopper of the decanter or at the edge of a wine-glass." It is fortunate for us that mosquitoes like most other creatures have their enemies; but, unfortunately, these foes are not sufficiently bloodthirsty or are without sufficient energy to do much in checking the crowds which feast upon our blood in so many parts of the world. The larvæ are pursued and enjoyed by fish; and the introduction of fish into pools suspected to harbour the insects has been often advised as a precautionary measure. Mr. Budgett, who has lately made two expeditions to the Gambia in order to investigate the development of certain fish, found himself immune from malaria owing to the fact, as at least he interpreted it, that the available standing water near to the scene of his labours had been carefully stocked with the fry which he was engaged in examining. Birds take their toll of the mosquitoes and the fierce dragon-fly catches them, as it does other insects, upon the wing. The proverbial fly in amber is often a mosquito; and in those early days there were clearly less chances of tasting human blood, so that the appetite has plainly developed recently. Still more so in the case of "a wingless gnat" described by Brodie from the Purbeck beds, a geological stratum which is of course of mesozoic age and long antedates the appearance of man upon this globe. Of all of these and of other matters does Mr. Theobald treat in his extensive monograph. The structure of the flies is illustrated by "process" blocks in the text; the use of these has led to the employment of smooth glittering paper which is not quite satisfactory and is even a little trying when the volumes are studied by artificial light. The various species are largely illustrated in a series of very beautiful plates which fill the third and smallest volume of the three. These plates are coloured and their execution can hardly be too highly praised.

---

[1] Proceedings of the Royal Society, No. 468, p. 267.

A Text-book of Physiology. Edited by WILLIAM H. HOWELL, Ph.D., M.D., Professor of Physiology in Johns Hopkins University. Vol. II. London and Philadelphia: W. B. Saunders and Co. 1901. Pp. 553. Price 13s. net.

THE subject of physiology has become so vast, the constantly increasing mass of its literature is so great, that few even amongst the best teachers find themselves competent to write to their own satisfaction on all its branches. The contributions of skilled physiologists to the English journals may perhaps be read through and understood in the course of two or three evenings, but many of the articles in such periodicals as Pflüger's *Archiv*, Hoppe Seyler's *Zeitschrift für Physiologische Chemie*, and Dubois Reymond's *Archiv* cannot be thus lightly dismissed. Few men are so familiar with foreign languages as to follow the thread of a long argument with the same facility that they can pursue it when written in English. It would not be difficult to indicate several recent articles in each of the above journals that require very close and prolonged attention to enable the statements of the author to be thoroughly understood. It is not surprising, then, that when a new text-book is contemplated even the most accomplished writer should shrink from attacking every branch and should prefer to call upon those who have made special study of each department, reserving for himself one or two in which he is specially interested. This practice has been adopted by Professor Schäfer in his recently-completed "Text-book of Physiology," by Richet in his "Dictionnaire de Physiologie" now in course of publication, and by Professor W. H. Howell in the fine work before us.

A large portion of the first volume, to which we called the attention of our readers a few months ago, was written by Professor Howell who was the author of the articles on Blood, Lymph, Secretion, Digestion, Nutrition, and Movements of the Alimentary Canal, Bladder and Ureter; that on Respiration and Animal Heat was written by Dr. E. T. Reichert; that on Circulation by Dr. John G. Curtis and Dr. W. T. Porter; and that on the Chemistry of the Animal Body by Dr. Graham Lusk.

The present, second, volume contains the following articles. The General Physiology of Muscle and Nerve and Special Muscular Mechanisms, by Warren P. Lombard, professor of physiology in the University of Michigan; the Central Nervous System, by Henry H. Donaldson, professor of neurology in the University of Chicago; the Special Senses, by Henry P. Bowditch, professor of physiology in the Harvard Medical School, and Henry Sewall, professor of physiology in the Denver College of Medicine, medical department of the University of Denver—the former writer taking vision and the latter the ear, cutaneous and muscular sensations, the equilibrium of the body, smell and taste, and voice and speech; and finally, Reproduction, by Frederick S. Lee, adjunct professor of physiology in Columbia University.

The long and carefully written article by Professor Warren P. Lombard on the General Physiology of Muscle and Nerve in the second volume is interesting from many points of view. In considering the subject of fatigue in particular he sums up the results of the numerous experiments that have been made of late years by Mosso, Lombard himself, Lee, Maggiora, Waller, Bernard, Hodge, and others. The cause of fatigue is not even yet quite clear. Raymond, a recent authority, for example, explains it in the case of the muscle-nerve preparation on the supposition that the destruction of the muscular tissue predominates over its anabolism or building up and that consequently after a time its contractile power is lost; but he immediately adds that fatigue also results from the accumulation of the products of contraction, sarcolactic acid and acid potassium phosphate which to a certain extent act in preventing contraction but being removed during a period of rest enable the contractile power to be recovered. In the fatigue of muscle following volitional exercise the cause is chiefly in the voluntary motor cells. Professor Lombard, however, very justly remarks that not only the muscles employed in work but other muscles, even when kept at rest, have their irritability reduced, which would suggest that the fatigue which finally asserts itself is due to some general, rather than local, influence. No reference is given by Professor Lombard to the remarkable observations on the microscopic changes in fatigued and exhausted muscle made by H. M. Bernard and C. F. Hodge.

Professor Donaldson in his article on the Central Nervous System gives a good *résumé* of the numerous experiments that have been made by Goltz, Ferrier, Schrader, Schäfer, and others, elucidating the functions of the several parts of the encephalon. On turning to the account of the cerebellum to ascertain whether any advances have been made in our knowledge of the functions of this remarkable organ it is astonishing to find how limited that knowledge is. Many of the statements made in the older treatises are no longer admissible and have been gradually eliminated, but little of a positive nature has been added. The cerebellum is a mine for research that has yet to be explored. Looking at its size, its great complexity of structure, and its extensive connexions with other parts of the nervous system, it is hard to believe that it is merely associated with the proper contraction of the muscles and the maintenance of the equilibrium. Professor Donaldson devotes a little more than one page to its consideration, but observes in the first paragraph of his account of it that it is almost as variable in its development amongst the vertebrata as the mantle of the cerebral hemispheres, and that in many fish and mammals it is asymmetrical in its gross structure. Where this variety exists the actions and movements and sensory endowments of the animals should obviously be subjected to close scrutiny.

The Physiology of the Special Muscular Mechanisms has been intrusted to the hands of Professor Warren Lombard of Michigan and Professor Henry Sewall of Denver who give a short account of the joints, the method of action of muscles upon the bones, and the mechanism of the different positions of the body in standing, walking, and running The greater part of this section is devoted to voice and speech A curious case is described of a pupil of Professor Sewall who possesses a whistling register in his larynx having a range of about one and a half octaves. The lips have nothing to do with this sound and no other tones can be produced simultaneously with it.

Professor Lee's article on Reproduction describes the process as far as to the formation of the placenta, but the author does not attempt to give any account of the development of the several parts of the embryo The various doctrines that have been advanced to explain the phenomena of heredity are very concisely but well given. He cannot accept Darwin's theory of pangenesis.

Professor Bowditch of Harvard University, under the heading of the Senses, without contributing much that is novel, gives a description of each sense that is thoroughly intelligible and supplies, especially in the case of the hearing, some good and original drawings.

By the selection of a large octavo page the editor and the authors of the several articles have contrived to introduce a very large amount of information in the 1100 pages at their disposal. The illustrations are clear and good and are fairly numerous. The present volume contains 229. There is a remarkably good index. We are of opinion that this is one of the best as well as least expensive treatises on physiology that has yet appeared.

Clinical Pathology of the Blood By JAMES EWING, A.M., M.D., Professor of Pathology in Cornell University. Illustrated with 30 Engravings and 14 Coloured Plates. London. Henry Kimpton. 1901. Pp. 432. Price 18s.

THIS volume is concerned with a branch of clinical pathology which is rapidly assuming a position of considerable importance in the educational curriculum of medical students. Within the last few years great advances have been made in our knowledge of the pathology of the blood and several critical works on this subject have been published; but knowledge grows apace, and at the present time few of them are altogether suited to the purposes of teaching or for the requirements of the present-day clinician; moreover, it must be remembered that a large proportion of the more recent contributions to this comparatively new science remain buried in the archives of foreign societies and medical journals until some enterprising author such as Professor Ewing sifts the wheat from the chaff and includes in book-form all that is really important to the student. Immense pains have obviously been taken in the compilation of this book to bring the subject with which it deals completely up-to-date, and for those who desire to pursue the study of any particular subject beyond the scope of the author's scheme a most elaborate bibliography is appended at the end of each chapter For the convenience of different classes of readers all matter of importance is embodied in the main text, while abstracts of special articles of theoretical or academic interest are printed in small type for occasional reference. The general design of the book is excellent: the opening chapter describes the practical technique of the various methods employed in hæmatology. The particulars and minute description of these methods have evidently been written with a view to assist the student who has to work without elaborate resources. This is a feature which will commend itself to teachers in many of our own pathological laboratories in which the equipment is not always on a generous scale. The subsequent chapters of Part I. are concerned with the chemistry, morphology, and physiology of the blood, in those the results which have been, or may be, attained by the application of the methods already described are referred to in detail and their bearing on clinical diagnosis is fully indicated. The second part contains an account of the diseases themselves to which the methods of hæmatology are applicable These diseases are divided into groups or natural orders and particulars are supplied for the differentiation of the members of each group by the simplest and best methods of examination. As each disease comes under consideration the blood condition is systematically described with reference to its physiological, morphological, chemical, and physical characteristics, and in those cases in which micro organisms play a part the bacteriological aspect of the disease is given in detail—in fact, full instructions are supplied in each case for establishing a diagnosis by the expedients of hæmatology Taking, for example, enteric fever as a typical example of a disease in which such methods have been proved to be of value, we find in the first paragraph of the chapter which discusses this disease a general description of the blood as a whole. The succeeding paragraphs are concerned respectively with the general characteristics of the red cells, of the leucocytes, and of the other formed elements in the blood. Next are described the variations which occur in different types of this disease with respect to the several elements of the blood, as also are the changes which occur under treatment and as the result of complications. Then follows the application of the information thus acquired to the purposes of diagnosis and prognosis, and finally the bacteriological features of typhoid fever are briefly alluded to.

As would naturally be expected, great importance is attached to the value of the "blood count." This is a trump card in hæmatology, since the evidence it affords is more trustworthy than that of a purely chemical or physical examination. The author draws largely upon the writings of Ehrlich in his description and classification of leucocytes and on those by Rieder in the nomenclature of white cell pathology Among the new words which have been invented for descriptive hæmatology we notice the term "eosinophilia," which is applied to the condition of the blood which is characterised by an excess of eosinophile cells. This example of the new nomenclature does not appeal to us as altogether satisfactory, though there is more to be said in its favour than for the abbreviated form of eosinophile cell—namely, "eosin"—which is generally used by Professor Ewing. It is to be hoped that this objectionable term will not creep into British literature.

Far less satisfactory are the chapters which are confined to the purely chemical side of hæmatology, but this is no fault of the author, for at the very threshold of the subject we are faced with difficulties which have not so far been overcome. For instance, the estimation of the alkalinity and basic capacity of living blood—a fundamental requirement for further chemical investigation—can at best only be determined approximately. In view of the influence of alkalinity on the absorption of carbonic acid by the blood and again of carbonic acid exchange in many pathological conditions, it is greatly to be regretted that this department of hæmatology is of so little practical use at the present time.

The illustrations, both coloured and uncoloured, especially those which show the congregating cycle of the tertian malarial parasite and the cells of blood differentiated by triple staining, are excellent and for the most part original. With the exception of the statement which appears on page 286, and which is to the effect that the blood of rheumatic fever is sterile, it is difficult to find any opening for adverse criticism either as regards the general design of this book or its execution.

Lehrbuch der Gynäkologie. (*Text-book of Gynæcology.*) By Professor MAX RUNGE. With numerous Illustrations in the text. Berlin: Julius Springer. 1902. Pp. 468. Price 10 marks.

THIS text-book of Professor Runge is written with a true conception of the place that modern gynæcology should take in medical practice. It is not sufficient, as we are told in the preface, to treat merely the local disease, it is usually necessary also to treat the patient herself. The tendency of gynæcology is so much towards a narrow specialism that such a warning is by no means out of place at the present day. The best gynæcologist is he who is also a general physician and who is therefore in a position to take a comprehensive view of the condition of the patient as a whole. Written in such a spirit the book cannot fail to attract attention. It is a book of considerable merit and the author has carried out his design with success.

The chapter on the Diet and Special Hygiene of Women is written clearly and concisely and in it useful rules as regards personal habits and other matters are laid down for the guidance of women at the different periods of their life. Professor Runge lays particular stress upon the importance of physical exercises for young girls to be carried out whenever possible in the open air.

In the chapter on Displacements of the Uterus he points out that the round ligaments would hardly contain so much muscular fibre did they not play a more important part in the maintenance of the normal position of the uterus than some writers credit them with. The inflammatory conditions in the pelvis producing acquired anteflexion of the uterus are regarded as of more importance than the displacement itself, and support is given to the view that the condition is really one of pathological fixation of the uterus, a view which enables the surgeon to form a better idea of the prognosis and treatment of the disease than if he regards it primarily as one of the varieties of displacement of the uterus. For bad cases of prolapse treatment by ventrofixation combined with plastic operation upon the vagina and perineum is recommended.

The chapter on Metro-endometritis of the Cervix and Body of the Uterus is very complete and gives a good account of the best methods, medical and surgical, of treating such cases. In considering the operative treatment of cancer of the uterus the surgeon is warned to give due consideration to the fact that women with a carcinoma of the uterus, the complete removal of which is a matter of doubt, often live a long time, whilst a difficult hysterectomy, especially if carried out through the abdomen, is attended with a very considerable risk to life without giving the patient any sufficient guarantee, even if she recovers, that she will enjoy any long immunity from recurrence.

The illustrations are good and the book is one of reasonable dimensions.

LIBRARY TABLE.

An Industrious Chevalier. By S. SQUIRE SPRIGGE. London: Chatto and Windus. 1902. Pp. 311. Price 6s.—Dr. Sprigge's book starts well from the very title. Readers of Perrault will remember the "morality" which that prince of story-tellers affixes to the immortal tale of "Puss in Boots":—

> "Quelque grand que soit l'avantage
> De jouir d'un riche heritage,
> Venant a nous de père en fils ;
> Aux jeunes gens, pour l'ordinaire,
> L'industrie & le sçavoir faire
> Vallent mieux que des biens acquis."

Dr. Sprigge's Chevalier and the hero of "Puss in Boots" both exhibit the same kind of industry, merely differing in degree. The former had only his own unaided talents upon which to depend, while the industry of the latter mainly consisted in corroborating the unblushing lies told by that very astute animal the cat. He received his reward in a princess and half a kingdom, while Dr. Sprigge's hero retired with a modest competence to a rural retreat in Essex. With regard to the manner in which he made this competence we must refer the reader to the book itself which will be found delightful reading. It is naturally difficult for us to say much about a work written by one so closely connected with ourselves as is Dr. Sprigge, but we may remark that the author of "The Life and Times of Thomas Wakley" in the work before us gives evidence of great versatility, while his knowledge of medical life and medico-legal situations is turned to excellent account.

JOURNALS AND MAGAZINES.

Annals of Ophthalmology: a Quarterly Journal and Review of Ophthalmic Science. Edited by H. V. WÜRDEMANN, Milwaukee. St. Louis, Mo., U.S.A.: Jones H. Parker. Vol x., No. 4, October, 1901; Vol. xi., No. 1, January, 1902. Price $4 per annum.—The articles contained in this well-conducted journal—each of the parts of which run to about 150 pages—are both numerous and interesting. The October number contains a translation of an article by Dr. Hugo Woff of Berlin, entitled "Observations with the New Electric Ophthalmoscope," the advantages of which are strongly insisted on. Dr. M. F. Weymann of St. Joseph, Mo., in another article gives the Pathogenetic Eventuations of Chalazial Tumours The editor of the *Annals* gives the Treatment of Recent Embolism of the Retinal Arteries by Deep Massage, with a report of two cases of embolism cured by this method. Dr. L. Steiner of Soerabaya, Java, contributes an article on Trachomatous Spots in the Malay in which he states that trachoma in the Malay is accompanied in many cases with pigment patches on the conjunctiva. Dr. F. O. Heath of Indianopolis, Ind., describes a case, with a drawing, of Amblyopia from Carbon Bisulphide Poisoning, a very rare affection. Dr. W. Campbell Posey of Philadelphia gives a case, with a drawing, of an Unusual Form of Superficial Punctate Keratitis. Dr. W. R. Broughton writes upon Residual Sensations as a Test for Diplopia or Heterophoria. Dr. R. Blysma of Middelburg, Netherlands, gives a brief account of a case of Opacities in the Vitreous associated with Amenorrhœa which was cured by rational general treatment. Dr. Albert C. Snell of Rochester, N.Y., gives a report of a case of Dermoid Cyst of the Iris not preceded by Trauma. Both numbers of the journal contain numerous abstracts from the ophthalmological literature of Germany, France, Russia, and other continental nations.

THE LANCET.

LONDON: SATURDAY, MAY 10, 1902.

The Royal Colleges in England and the General Medical Council.

IN another column we publish the report made by Dr. NORMAN MOORE, the representative of the Royal College of Physicians of London on the General Medical Council, upon the proceedings of the Council at the special session held in February of this year. The importance of the questions involved is so great that we make no excuse for recapitulating the various events that our readers may fully appreciate how the matter stands. It will be remembered that in December last at the winter sitting of the Council for 1901 a committee of the Council was appointed to prepare a report on the differences existing "between certain licensing bodies on the one hand and the General Medical Council on the other regarding the courses and conditions of study and the recognition of the institutions and schools in which the required courses may be taken." We have on more than one occasion referred to the unfortunate, and unfortunately acute, divergencies of opinion which have arisen between certain of the licensing bodies, notably the Royal College of Physicians of London and the Royal College of Surgeons of England, and the central authority in the kingdom respecting the education of our medical students. We took it on ourselves to make certain suggestions that we believed would pave the way for an amicable settlement but we do not see many signs of the disputants approaching one another; nor can the proceedings at the special session of the Council, which were fully reported in our columns during the sitting, be described as constituting a peace congress.

The main point at issue between the parties is of course that the General Medical Council claims a right to select the institutions in which the preliminary scientific studies of the medical students of the various curricula may be undertaken after the students have registered. The General Medical Council has, in fact, refused to recognise certain institutions which, after investigation, have been accepted as suitable places of study by the two Royal Colleges. The Council at the special session in February received the report of the committee appointed to investigate thoroughly the delicate matter at issue, but the meeting was productive of no final settlement. The committee issued eight recommendations. All of these formed more or less interesting reading but several were of such a nature as to be obviously doomed to failure. The first five recommendations stated with some particularisation that in consequence of the differences of the methods under which students, working under varying regulations, are accepted as candidates for examinations, the qualifications of certain universities and licensing bodies do not ensure that the persons holding the qualifications possess the requisite knowledge and skill for the efficient practice of their profession. Included in this list were the University of Oxford, the University of London, the Royal College of Physicians of London, and the Royal College of Surgeons of England. A further clause recommended that the Council should, after preliminary warning, represent this fact to the Privy Council with a view to deprive the above bodies of their power of granting qualifications to practise unless they altered their regulations with regard to the preliminary training of their students. It is no matter for wonder, therefore, that the tone of the discussion of the recommendations at the special session was not completely favourable to the adoption of the report. The most important of our corporations and the most ancient and learned of our universities are as much bound in honour and in law to assist the General Medical Council to keep medical education at a high standard as are the most recent and least influential of the qualifying corporations. But while the Council recognised this—as do all of us—it could not, sitting in conclave, seriously suggest that the bodies which we have named should be threatened with the intervention of the Privy Council, unless the clearest proofs of culpable obstinacy or wilful blindness to the needs of the student were forthcoming. It is no matter of surprise, therefore, that Dr. D. C. MCVAIL, chairman of the committee, asked leave of the Council to withdraw the recommendations, while the leave was granted without a division. The Council then resolved to request the Conjoint Board of the Royal Colleges of Physicians of London and Surgeons of England to furnish it with certain information regarding the courses of study in the preliminary subjects which the Royal Colleges required and also regarding the steps which were taken to ascertain whether the various schools and colleges recognised by the Conjoint Board were worthy of that confidence. Dr. NORMAN MOORE, who with Mr. T. BRYANT sat on the committee and signed a minority report dissenting from the recommendations, gave an undertaking that the Royal Colleges would furnish the utmost possible information to the Council. And so the matter was left.

Dr. NORMAN MOORE has now made a report to the Royal College of Physicians of London upon the situation that has been created. It will be observed (see p. 1354) that he adheres to the position of independence claimed by the corporation which he represents. He points out that in his opinion the Council has no power of visitation of institutions and no power to compel the Colleges to visit the institutions which they recognise for any part of the course. If this be so it seems doubtful whether the Council has power to demand under the Medical Act the information which he has undertaken shall be supplied. However, he thinks that the Royal College of Physicians of London would be acting rightly in furnishing what is requested of them. We entirely agree with him. We have before urged on both the parties the obligation to give and take a little, and in acting as Dr. NORMAN MOORE suggests the Royal College of Physicians of London, without in the least departing from the dignified position it has rightly assumed, might give information which would greatly help to bring matters to a satisfactory issue. The Royal Colleges devote a great amount of time and trouble to visiting and revisiting the institutions which they recognise for preliminary study and if the laboratories or teaching staffs do not, in the opinion of the visitors, reach the necessary standard the school or college is not added to the list. If the defaulting institutions are already on the list and are found to have deteriorated to such an extent as no longer to satisfy the requirements of the Royal Colleges their names are removed. We believe, therefore, that the General Medical Council may, without sacrificing any of the power which it claims to hold over the examining bodies of the United Kingdom, meet the Royal Colleges in this respect by acknowledging these institutions and so end the *impasse* which now exists. We should not make this suggestion if we thought that there was the slightest danger of the central authority being jeopardised by the concession. In concluding his report Dr. Norman Moore states that he has endeavoured to make clear to the Council that as the powers of the Royal College of Physicians of London as regards its own curriculum rest not only upon Acts of Parliament and charters but also upon its obvious competence to deal with questions of medical education, it cannot permit any encroachment upon its sphere of responsibility, but that it will always in the future, as it has since the General Medical Council came into existence, do all in its power to aid the Council in the duties which the Medical Acts have prescribed for it. We trust that the approaching session of the General Medical Council will result in harmony being restored between parties to a quarrel who have one and the same object in view—namely, the furtherance of medical education.

The Coal Smoke Abatement Society and Domestic Grates.

The Coal Smoke Abatement Society is a most useful institution which has not received from the public anything like the attention which it deserves. Especially would we urge upon medical men that the work upon which this society is engaged is worthy of their support, for the part that is played in pathology by the murky atmosphere of London and other of our great cities can hardly be exaggerated. The society needs more subscribers and its justification in asking for them lies in its published work. A glance at the balance-sheet of the society, issued with the last annual report, shows that the small sum which has been placed by the public at the disposal of the executive has been most judiciously used. Unlike many other somewhat similar societies nothing has been wasted in the multiplication of direct or indirect advertisements, but the money has been spent in actual and valuable work, often of an arduous and delicate nature. We have chronicled in our columns a good many examples of the society's activity; especially we have called attention to its vigorous support of actions instigated by the metropolitan boroughs, or late vestries, against the owners of foul factory chimneys. We have felt, however, when recording with pleasure the fining by magistrates of those responsible for smoky factory chimneys, that it was not exactly fair that the domestic chimney should be permitted to create a nuisance with impunity. A factory chimney will produce a much more imposing volume of black smoke than a domestic chimney, but the numerical proportion of domestic chimneys to factory chimneys is out of all proportion large, and it is unjust to saddle the factories with all the damage that is done to our health, our public buildings, our works of art, and our gardens by coal-smoke. The domestic chimney plays its wicked part in adding to the virulence and opacity of fogs, and to reform the domestic chimney would preserve plant life where it now often succumbs, and would allow trees and shrubs to show the town-dweller some of the beauty of nature's differing shades of green, instead of presenting merely a grimy monochrome of sooted leaves and blackened bark. And, which is far more important than æsthetic considerations, such reform would have an enormously beneficial influence upon our health statistics. We are glad, therefore, to see that the Coal Smoke Abatement Society has projected an inquiry into the subject of domestic grates and has undertaken the task in exceptionally favourable circumstances. The control of the production of coal smoke in large towns is obviously a big question and really important results must await probably the active assistance of the Government. Such assistance has already, we see, been forthcoming in the investigation which is fully described at p. 1342 of this issue. The object of this investigation was to discover a grate which would permit the domestic use of smoky coal without the accompanying smoke that is now provided by thousands of private chimneys. As the report says, there is no expert on the subject and no manufacturer of grates has turned his attention to the production of a smokeless form of grate, while at the same time the great majority of householders are at present unwilling to accept anything but open grates burning smoky coal. The Coal Smoke Abatement Society therefore instituted an investigation into the subject of domestic grates, inviting manufacturers by advertisement to offer their grates for the tests. The work has been excellently planned and energetically carried out by Dr. H. A. Des Vœux, the treasurer of the Coal Smoke Abatement Society, and the late Mr. Bryan Donkin, by whose recent death the Institute of Civil Engineers and the Institute of Mining Engineers have suffered a heavy loss. From the charts accompanying the article our readers will gather the facts elicited and also will see at a glance the order of merit in which the grates that were submitted for examination stand. It is to be regretted that so few manufacturers answered the invitation and that therefore it cannot be asserted even that the best grate in the market has been demonstrated. Moreover, one important difference between the conditions under which the grates were tested and those under which the domestic grate is ordinarily used provided a fallacy in the results. The grates were stoked so that the fire never fell below a certain level—that of the top bar. In actual everyday use this, of course, would not obtain and a grate that was comparatively smokeless with so constant a fire might be extremely smoky when the fuel was much less regularly provided. The investigation, however, demonstrates marked differences between the coal-absorbing and the smoke-supplying properties of various grates, and the Coal Smoke Abatement Society may well be encouraged by the results of its experiments.

The London Water Bill.

MR. LONG has doubtless been surprised at the treatment meted out to his Bill by the Joint Select Committee which was appointed to consider it by the two Houses of Parliament. We cannot say that we also are surprised. At the eighth sitting of this Committee it was decided to delete the representation of the metropolitan boroughs from Schedule E of the Bill and to delete also the representation of the urban districts and of all the boroughs in the counties of Essex, Middlesex, and Surrey, with the single exception of the borough of West Ham. The promoters of the Bill, Mr. LONG, Mr. RITCHIE, the Attorney-General, and Mr. GRANT LAWSON, were, moreover, requested to prepare a fresh schedule on the plan indicated by this decision of the Committee for a Water Board consisting of about 35 members, including the chairman and vice-chairman, but without giving a majority of the Board to the representatives of any one county. It was announced by Lord BALFOUR of BURLEIGH that this was not a unanimous decision but was that of a majority of the Committee. It was inevitable that the Government should make a move in defence of the Bill, and accordingly on Tuesday last Mr. J. D. FITZGERALD, counsel for the Local Government Board, but speaking expressly as the mouthpiece of a regretful Government, urged upon the Committee to reconsider its drastic resolve. To this course, upon consideration, the Committee agreed, and a decision, presumably a final decision, is promised after an adjournment until Monday next.

The schedule which was referred back to the promoters of the Bill provides solely for the representation of authorities on the Water Board, and the authorities named are classified under the counties in which they have jurisdiction. Representation is given also to the Conservators of the Thames and to the Lee Conservancy. It cannot be said that under the Government scheme the metropolitan boroughs were inadequately provided for, for six of the larger boroughs were to have two representatives each and the remaining boroughs one representative each. In THE LANCET we have from the period of their creation constantly urged on the representatives of the London boroughs the importance of the privileges entrusted to them, especially those concerning the water-supply. Had they shown a just appreciation of their duties they would have taken the precaution of being adequately represented before the Joint Select Committee when their claims to representation on the proposed Water Board would not have been deleted, whether only temporarily or permanently remains to be seen, with the stroke of a pen. It is, of course, possible that the metropolitan borough councils thought that they had done all that was required of them to vindicate their position when they passed resolutions and forwarded copies of them to the President of the Local Government Board. Mr. RAM, K.C., stated at the eighth sitting of the Committee that metropolitan borough councils representing 2,500,000 people were in favour of the Government proposal and that those opposed to it represented 500,000 only of the population. The metropolitan boroughs may, it is permissible to conceive, have thought that they were safe in leaving their case in the hands of the Local Government Board, but the attitude of the Joint Select Committee must have opened their eyes.

Some of the witnesses who gave evidence before the Joint Select Committee stated their opinion that the provisions made for the election of representatives on the proposed Water Board were more unsatisfactory than were those contained in the Bill which Lord JAMES of HEREFORD introduced in the year 1896. This Bill, which was entitled the "Metropolitan Counties Water Board Bill," was of a more simple character than is the present Government measure. It contained no more than 10 clauses and occupied only four pages. The composition of the Board proposed by Lord JAMES has now received the modified approval of the Right Honourable G. J. SHAW LEFEVRE, late President of the Local Government Board, and of the Parliamentary agent of the London County Council. Under Lord JAMES'S scheme the London County Council was to appoint 16 members, the City of London, the county councils of Middlesex and Essex, and the borough of West Ham two members each, and the county councils of Hertford, Kent, and Surrey, the borough of Croydon, the Conservators of the River Thames, and the Lee Conservancy one member each. Lord JAMES'S proposal, therefore, was to give a majority on the Water Board to the London County Council and the opposition to the measure was on that account so general and so strong that the Government had to drop it. The Joint Select Committee which is now sitting, in returning the present Water Bill for revision, by advising that the proposed Water Board should not contain a majority from any one county, has evidently tried to induce Mr. LONG to avoid the error which wrecked Lord JAMES'S Bill. But neither Mr. LONG nor the Government sees the matter in that light.

The Government Bill, as we have already pointed out, pleases no one. In one respect Lord JAMES'S Bill was infinitely preferable to Mr. LONG'S Bill. The Water Board proposed by Lord JAMES would not have been compelled to buy the present defective undertakings of the metropolitan water companies. It would not have been in its first unprotected infancy thrust with tied hands into a series of expensive arbitration cases for which it was entirely unprepared, and this may well be the fate of the Water Board if it should be constituted according to Mr. LONG'S scheme. On the contrary, Lord JAMES'S Water Board would have had power to inquire into and to enter into negotiations, to make and to adopt provisional agreements respecting any matters relating to the water-supply, and to take such steps for promoting or opposing any Bills in Parliament as might appear to the Board necessary or expedient in relation to the water-supply. There is a homely country proverb which expresses the idea that it is always inexpedient at market to purchase an animal which is protected from observation by an extraneous covering. The popular phraseology of the adage should be known to Mr. LONG, but the Bill which he has introduced shows that he has made no use of the teaching which it conveys. Happily, he still has time to reconsider his position and we trust that the value of the water companies' undertakings will be accurately ascertained.

The proceedings of the Committee have resulted in the production of some interesting evidence. We now know that Mr. LONG'S Bill was drawn up by a secretary or assistant secretary to the Local Government Board and that the gentleman selected for this work had, according to his own account, no practical knowledge of matters pertaining to water-supply. Counsel who appeared on behalf of the Local Government Board stated that the Bill was drawn up on the recommendations of the recent Royal Commissions on London Water. In the case of the Balfour Commission, however, counsel did not add that the evidence given to the Commissioners in regard to the amount of water available has since been proved inaccurate. The Balfour Commission gave its report on the strength of this evidence and is not too severely to be blamed because it was misled in matters of fact. Nor, on the other hand, can an expression of opinion founded on erroneous data be treated as gospel—perhaps it should be classified as apocrypha, a designation suggested by Lord LLANDAFF in regard to some of the dicta of the Balfour Commission. The statement made by the counsel for the Local Government Board that the Water Bill was in accordance with the Llandaff report was promptly disposed of by Lord LLANDAFF, whose opinion it was that the water-supply of the metropolis could be best carried on by men who had a practical knowledge of the matters pertaining to the supply of water.

Annotations.

"Ne quid nimis."

TYPHOID FEVER AND PREGNANCY.

THOSE of our readers who have followed the course of the illness of the Queen of Holland will not have been surprised to hear that she has had a premature confinement. Typhoid fever complicated by pregnancy is always a condition of great gravity, although, happily, the old view taught by Liebermeister and others that these cases always have a fatal issue is no longer held Cazeaux was the first to combat this teaching and further experience has shown it to be false. The mere presence of the fœtus in utero does not appear materially to affect the course of the fever but it exposes the patient to all the dangers of a premature delivery. This results in from 63 to 83 per cent., or in about two-thirds of all the cases. The likelihood of its occurrence depends partly upon the stage of the pregnancy and partly upon the severity of the attack of the fever. It occurs more frequently in the early than in the later months of pregnancy and more frequently when the general disease is running a severe than when it is running a mild course. In some cases, no doubt, the fever causes the death of the fœtus, in other cases hæmorrhages occur into the decidua, hæmorrhages similar to the so-called "uterine epistaxes" of Gubler which occur from the uterus in patients suffering from typhoid fever who are not pregnant, while in other cases, again, the typhoid bacilli or their toxins find their way directly into the fœtal blood and tissues In 1841 Manzoni published a case in which he found what he thought were characteristic typhoid ulcers in the intestines of a fœtus born at seven and a half months and dying some 30 minutes after its birth. Eberth, Widal, and others have demonstrated the typhoid bacillus in the blood of the placenta and also in the blood and tissues of the fœtus. Of late years further proof of the transmission of the poison has been shown by the recognition of fœtal typhoid fever. In a case recorded by Ernst the fœtus lived for 93 hours and the typhoid bacillus was found in the spleen, the brain, and in the marrow of some of the bones. Quite recently, too, Widal's reaction has been obtained in the blood of the fœtus and it has been shown that various degenerative and sclerotic changes can at times be found in the tissues of a fœtus born of a mother suffering from typhoid fever. These are no doubt due to the action of various toxins and may be the cause of the death of the fœtus in certain cases. A question of much importance in connexion with the illness of the Queen of Holland is the effect of the occurrence of a miscarriage upon the prognosis of the disease. An early abortion appears to involve more danger than a premature delivery, no doubt owing to the greater likelihood of severe hæmorrhage occurring in the former instance. The danger, however, depends most of all upon the stage of the disease at which the pregnancy is interrupted. The earlier the contents of the uterus are discharged the better, no doubt because the patient's strength is not yet greatly reduced. Goldschmidt found that death occurred without abortion in 3·1 per cent. of the cases, after abortion in 27·5 per cent., while recovery took place in 25 per cent. without abortion and in 44 per cent. after abortion. In 38 cases collected by Duguyot in patients before the seventh month of pregnancy 18 recovered after aborting, while 13 recovered without aborting. The prognosis in any given case will depend upon the duration and the severity of the fever, the duration of the pregnancy, and the presence or absence of severe hæmorrhage or septic infection following the delivery. Gusserow considers that these patients are especially prone to septic poisoning, and no doubt this is true in so far that their powers of resistance must be greatly lessened. The treatment of these cases does not differ from that of any ordinary case of typhoid fever. If premature delivery occurs the great danger which the patient runs from hæmorrhage or septic infection must be borne in mind and every means must be taken to diminish the strain of the delivery as far as possible.

THE INVESTIGATION OF CANCER.

THE recent appeal for £100,000 to be devoted to the investigation of cancer has stimulated our lay contemporaries to draw the attention of the public to the continuous extension of malignant disease and to the urgent need of a careful and thorough study of malignant growths. The articles have been numerous and for the most part sound, useful, and likely to stimulate generosity. In an article published in the *Morning Post* of May 2nd there is, however, an attempt to explain to the public the whole *modus operandi* of a malignant tumour in which the writer rather loses himself in describing the how and the why of the growth of a cancer. He starts with the statement that the "working hypothesis" now generally accepted by investigators is the autositic theory. This is certainly not in accord with facts. There are, it is true, a few pathologists who still cling to the autositic theory, but the tendency at the present time is certainly to accept the microbic hypothesis, and those who have done most within recent years to advance our knowledge of the subject both in this country and abroad are investigating the subject chiefly from this aspect. The writer goes on to make clear to the lay mind what is meant by the "autositic theory." He explains that certain cells "rebel" against a weakened nervous system, indulge in a "cannibal diet" by feeding on the neighbouring tissues, form "colonies of autosites" in every part of the body, and so lead to death. This is all very pretty, but it is, at least so far as we know at present, pure imagination. The very basis of the whole theory is a weakening of the nervous system and we have absolutely no evidence at present that in malignant disease there is any change in the nervous system. Where the nerve supplying a part of the system is divided certain very definite phenomena appear, but there is no special proneness before a clinic of doctors and the late Professor Pepper, at the University of Pennsylvania, and they all pronounced my case incurable, as they said the stomach *was gone*; therefore nothing to build on; then I gave up in despair until I found one of your circulars, and, like a drowning man, grasped it, and I bless the event ever since, for you built me up beyond my hopes—yes, saved my life. To-day my stomach can digest almost any kind of food and I am in high hope of being a stronger man than ever I was. As you know, my case was a desperate one and I had lost all interest in life.' 'Mrs. B. C Copeland, Evansville, Ind, S S —I can truly say that I have been successfully treated and *cured* by you of diseases that the old school doctors have failed to cure and even went so far as to say I could *not* be cured. I am now almost 72 years of age and am feeling well and can stand more work than the generality of younger people and people who do not know me take me to be about 50 years of age. And in truth I must give the power of your mind the honour and credit of all my good health and youthful appearance. 10 years ago I was a perfect wreck—could not walk any distance without stopping for breath and strength I now can walk miles with comparative ease.' On the attractions of this system it were superfluous to enlarge To have one's stomach restored to one after it was 'gone'; to be able to digest 'almost any kind of food', never to need another dose of medicine; and to look 50 when one is really 72, these are boons not lightly to be esteemed. But what most attracted the pensive taxpayer over whom an impending War Budget begins to cast its shadow, is Helen Wilmans Post's treatise on 'The Conquest of Poverty' Of this its gifted authoress boasts, and probably with justice, that it is 'the most popular book in the range of mental science literature. It brings freedom to the mind, and through the mind to the body' With a steadily decreasing income and an expenditure pitched high enough to satisfy the social demands of Stuccovia, that is, indeed, a freedom devoutly to be wished but not, I fear, to be attained"—"In Praise of Birds," by E. V B, is written with all the charm of language which we expect from the translator of the "Story Without an End"

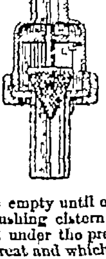
The Practitioner—The March number contains a paper entitled "The Health of the People" by Mr James Cantlie, in which he touches upon many points that concern the physical well being of the community He asks the question, "Why is town life so detrimental?" and considers that there are several reasons why such a state of affairs should exist The absence of fresh air in our cities is, of course, a potent factor and the disinclination to take exercise is a further detriment to good health. Mr Cantlie points out that the great health problems which immediately present themselves resolve themselves into two—namely, "How are we to maintain the health of our town-dwellers and the numbers of our country districts?" The former he considers to be impossible without, so far at any rate as the youths of the poorer classes are concerned, military conscription, and the latter requires improved conditions of living for those who till the soil Dr Arthur P Luff contributes an interesting paper on Gout, Observations on its Pathology, Forms, and Treatment, and Dr J A. Gibson gives some good illustrations of Graves's Disease. Dr F W Burton-Fanning's paper on the Etiology of Pulmonary Tuberculosis is also worthy of note seeing that it contains some original observations on the exciting causes of tuberculosis which have hitherto not been sufficiently recognised. For instance, he shows that physical over-exertion is a most powerful determining cause of the system's limiting or protective agencies against the disease.

The Quarterly Journal of Microscopical Science Edited by E. RAY LANKESTER, F R.S., ADAM SEDGWICK, F R.S., F. R. WELDON, F R.S, and SYDNEY J HICKSON, F.R.S. With Lithographic Plates and Engravings on Wood. London: J. and A. Churchill. New Series. No. 180 Vol. XLV., Part 4 8vo. Pp 60 Price 10s.—The following articles are contained in this number. 1. On the Structure of the Excretory Organs of Amphioxus, Part 1, by Edwin S. Goodrich, M.A, Fellow of Merton College, Oxford, with a plate Mr Goodrich describes the excretory tubules as forming a series which open into the atrium but not into the cœlom They are provided at their blind internal ends with a large number of solenocytes. He concludes from his observations that in their segmental arrangement, in their function, and in their histological structure the excretory organs of amphioxus and the nephridia of phyllodoce are in all essentials identical. 2. A contribution to the Morphology of the Teleostean Head Skeleton, based upon a study of the developing skull of the three-spined Stickleback (gasterosteus aculeatus) with four plates and five text illustrations; by H. H. Swinnerton, B.Sc. This is a very elaborate and carefully worked out description of the development of the skull of this little fish. 3. The development of Admetus Pumilio (Koch), a contribution to the Embryology of the Pedipalps; by L. H. Gough, with two plates. 4 On the Teeth of Petromyzon and Myxine; by Ernest Warren, D Sc. 5. Typhlorhyncus Nanus, a New Rhabdocœle; by F F. Laidlaw, B.A. This part completes vol. xlv and contains the index for that volume.

New Inventions.

(1) A CLOSED WATER STORAGE SYSTEM, AND (2) AN AUTOMATIC FLUSHING APPARATUS

1. Two sanitary appliances, the inventor of both of which is Mr Grundy of 13, King William street, London, E C., are deserving of attention inasmuch as they promise to remove many serious drawbacks to existing systems. To start with, the objections to an open storage system are well known, to overcome which it has been suggested to make the cistern a kind of expansion of the rising main, but hitherto this has not been found convenient Mr. Grundy, however, appears to have found a solution of the difficulty though we are not sure that his system does not present some practical obstacles. The cistern is completely closed and is placed sufficiently high to supply all the services in the house, the water passing from the main *via* the storage-tank without being exposed to the atmosphere. This is done in part by abolishing entirely the ball valve and substituting for it the check valve shown in the illustration Water passes upwards through this valve but cannot return. At the top of the cistern an outlet is provided at the foot of which is a valve float which, as soon as the cistern is full, checks an overflow while trapping the water in the cistern at the pressure of the main at that level In the event of the main supply failing the cistern contains a store which is easily drawn off, air gaining entrance at the float valve. The valves are of excellent workmanship and design and would replace with advantage the old and somewhat clumsy ball valve, while they avoid the exposure of the water to contamination from without 2. The automatic flushing apparatus is started in action either by the seat of the closet or by a foot lever acting on a two-way valve. The cistern is empty until either the seat or foot lever is actuated. The flushing cistern is closed, so that the water contained in it is under the pressure of the main which in most instances is great and which thereby effects a powerful yet comparatively silent flush. It is obvious that by this system the pollution of water by the return of foul air up the pipe is prevented, while the cistern being closed there can be no contamination from impure air coming into contact with the surface of the water. Both appliances are a decided advance upon



to the development of malignant growths and many other facts might be brought forward in opposition to the nervous hypothesis. We hold no brief on behalf of the microbic theory, but we cannot admit that the fact that "the subsidiary growths always have the organisation of the tissue in which the original colony is situated" is "utterly inexplicable" on the assumption that there is a specific microbe of cancer. It is not necessarily a bacillus that we are dealing with, as the writer of the article seems to imagine. A microbe living in a cell, multiplying rapidly and stimulating the cell to division, will explain fully all the phenomena of malignancy. Be this as it may, it is unwise to base the treatment of cancer on so unstable a foundation as the unproved autositic theory. The writer suggests that the profitable pathways of research are to find "some non-surgical means of strengthening the resisting power" of the tissues and "some means of causing disease in the colonies." We fear that there is not much to be hoped for in these directions. When we possess accurate knowledge of the cause of malignant growths our aim will be to prevent and not merely to cure cancer. It would be unduly optimistic to hope that within the next few years this knowledge will have been attained entirely, but we confidently look forward to progress.

THE WATER-SUPPLY OF ISOLATED HOUSES.

IN the *Builder* of May 3rd an article is devoted to the water-supply and drainage of isolated or detached houses. In such cases the rain-water is usually conveyed by a separate system of drains to an underground tank from which it is pumped to a cistern in the building. As a rule the roof of the house is utilised as a collector and two sets of drains, for sewage and rain-water respectively, must be laid. Unless care be taken there is, therefore, danger of the sewage-drain being connected to the rain-water drain with deplorable consequences. In a case known to the writer of the article the water stored in an underground tank for domestic purposes gradually deteriorated in quality until it became unfit for use. After a careful investigation it was discovered that the drain from a water-closet was connected with the rain-water system. This, the writer adds, was a new house, and if a mistake of this kind can be made during construction it can certainly also be made during subsequent alterations when the position of the two systems has been forgotten. The *Builder* is doing good service by drawing attention to the most common sanitary errors and defects connected with buildings in a series of articles intended for students but nevertheless of great general interest. When a drain is buried out of sight and reach it becomes a source of danger to the whole neighbourhood. There ought to be a manhole at every angle or change of direction in a drain, and it would be well if this safeguard were to be enforced by law.

REMOVAL OF SMALL-POX PATIENTS.

ON May 2nd the Divisional Court was moved on behalf of one Quelch, who had been convicted by Mr. T. J. Jones, one of the justices for Surrey, for obstructing the removal of his son who was alleged to be suffering from small-pox. It appeared that the medical officer of health (Mr. C. M. Fegen) had granted a certificate under Section 124 of the Public Health Act to the effect that the patient was suffering from small-pox and that there was no proper accommodation at the father's house. It was contended on the part of the father, who had endeavoured to prevent the justices' order from being carried into effect, that he had had no notice of any application for an order, that there was in fact sufficient accommodation at the premises in question, and that the magistrates were not justified in acting upon the certificate of the medical officer without more investigation. The court refused to grant any relief, the Chief Justice saying that the magistrates had exercised their discretion and that that could not be interfered with. We trust that this case may serve to emphasise the fact that the justices, acting through the medical officer of health, have an absolute discretion to order removal in every suspicious case, whether the step is taken for the protection of the patient or of those who may be exposed to infection. It is obvious that an order of this kind must be made *ex parte*, that a suspicion of small-pox must be sufficient to justify an order for removal, and that the justices must adopt the opinion expressed by the medical officer. Were it possible for parties to appeal against, or to appear and to give evidence in opposition to, an application for an order that section of the Public Health Act under which the orders are made would become a dead letter. It is also well for medical officers of health to bear in mind that they are under no personal liability if in granting certificates for removal they carry out the instructions of the local authority.

THE CAMBRIDGE MEDICAL SCHOOL.

DR. P. W. LATHAM has addressed to the members of the Senate of the University of Cambridge a remarkable memorandum concerning the medical school of the University. The medical school of the University of Cambridge is now one of the most important in the kingdom and Dr. Latham's memorandum is a wholesale indictment of its business arrangements. We shall be interested to see what steps are taken by the Senate of the University, which body must be fully aware that the medical school is an important branch of the educational tree. It is hardly too much to say that of late years the workers in the Cambridge physiological and pathological laboratories have constituted the best-known group of Cambridge scholars, while the praise that has been bestowed upon the medical school has been unstinted both at home and abroad. Consequently Dr. Latham's memorandum will come as a great surprise to many who have accepted the view that all was for the best in the best of scientific centres.

THE DIAGNOSIS OF CYSTIC KIDNEYS.

CYSTIC kidneys are seldom diagnosed during life. In *American Medicine* of March 22nd Professor William Osler points out that the clinical features are sufficient for diagnosis and he relates the following case. A woman, aged 28 years, who usually enjoyed good health, was admitted to hospital on Jan. 21st, 1899 About a year before the urine was blood-red for nearly a week. In December, 1898, she had for two weeks paroxysmal pain in the right side and the urine was bloody. She also noticed some distension of the abdomen. The prostration and weakness from loss of blood caused her to remain in bed for nearly three weeks. When she got up she noticed that her feet were a little swollen and that her eyelids were puffy. Since the attack micturition had been more frequent by day; sometimes it was performed at intervals of one and a half hours On admission she looked healthy but was rather sallow. The pulse was of increased tension. The radial and temporal arteries were sclerotic. The cardiac impulse could be felt in the fifth space in the anterior axillary line. The second sound was accentuated. Both flanks showed fulness and were occupied by large irregular tumours. The red blood corpuscles were 2,400,000 per cubic millimetre and the hæmoglobin was 40 per cent. of the normal. The urine was of specific gravity 1007 or 1008 and contained a trace of albumin and usually a few red blood corpuscles. Once a hyaline cast was seen. The quantity passed in the 24 hours was rarely more than a litre. Cystic kidneys were diagnosed. The patient left hospital on Feb. 11th, 1899, feeling comfortable She was readmitted on Feb. 27th, 1900, with urgent dyspnœa. She had remained well but had at times passed bloody urine. The dyspnœa had existed for four days. The thorax showed no signs of disease. In the throat were a few white patches which did not yield diphtheria bacilli. She became so cyanosed that tracheotomy was performed on Feb. 28th but without relief. The urine was of specific gravity 1013 and contained many red blood corpuscles but no casts. She gradually sank and died on March 1st. The necropsy showed greatly enlarged kidneys consisting of congeries of cysts. The left kidney weighed 1400 grammes and the right 950. There were marked cardiac hypertrophy and general arterio-sclerosis. The general characteristics of cases of cystic kidney are (1) bilateral tumours in the flanks (in only two out of 88 cases was the disease unilateral); (2) the cardio-vascular changes and urine of interstitial nephritis; and (3) hæmaturia which may occur in paroxysms and be associated with much pain. Diagnosis may be important, as the following case shows. A large cystic kidney was exhibited at a medical society. Professor Osler asked what was the condition of the other kidney and the surgeon said that he had not examined it as his attention was not called to it. The patient died in a few days with uræmic symptoms. As a rule, operation is contra-indicated, for removal of one kidney simply takes away one-half of the available renal tissue. But Mr. Henry Morris has successfully operated in cases of unilateral disease. He says that when the opposite kidney has been ascertained, either by inspection or palpation, to be unaffected the relief from pain and hæmorrhage and the immunity from the danger of suppuration offered by nephrectomy should not be withheld.

INTERMITTENT CLAUDICATION OR LIMPING.

DR. J. H. LEVY describes in the *Philadelphia Medical Journal* of April 12th last the rare and little known disease called "intermittent claudication" or "limping," which was first recognised by Charcot in 1858. Recent researches have tended to show that the disease is one of a neuro-vascular group of ailments which includes other rare affections, such as Raynaud's disease and erythromelalgia. Among the etiological factors, states Dr. Levy, might be included all conditions which produced arterio-sclerosis. Yet the curious fact remained that while arterio-sclerosis was a common affection, intermittent claudication was rare. The most common causes were alcohol, syphilis, undue exposure, and the excessive use of tobacco. The disease occurred almost exclusively in males, a fact which has been already alluded to in these columns.[1] Among the cases recorded by Dr. Levy is one of special interest as showing the relations between intermittent claudication and its allies, Raynaud's disease and erythromelalgia. It is as follows. A man, aged 33 years, a Russian subject, had malaria when he was 14 years of age. He suffered from whitlows on the fingers of his right hand at the ages of 14, 16, and 24 years respectively. At the age of 20 years he joined the army and had to undergo much hardship and exposure. At 25 years of age he emigrated to the United States and followed the occupation of a pack-pedlar. For several years he consumed about three ounces of whisky daily and smoked about four ounces of tobacco weekly. In the autumn of 1898 he suffered from pain in the right hip and over the sciatic nerve which grew worse at night. Later the pain spread to the knee and heel, first one knee and then the other being affected. In the spring of 1900 sharp pains developed in the big toe and cramps in the calf of the left leg. There was much difficulty in walking, for cramps came on after taking a few steps, stopping when he rested and recurring when he started to walk again. The right foot eventually became swollen and discolourations appeared about the heel and toes in the form of bluish spots. The skin in the affected areas was exquisitely sensitive and tender to pain and pressure. He also suffered from insomnia and had to remain in bed, being unable to walk. The foot was cold and dry and the bluish painful areas closely resembled those observed in Raynaud's disease. The muscles of the calves and thigh were wasted, especially on the right side. Pulsation was absent in the posterior tibial and dorsalis pedis arteries on both sides. He was treated with morphia (three grains daily) to relieve the pain, while bromides and iodides were given internally and massage and electricity were applied locally. The disease, however, progressed and gangrene followed in the fourth toe and big toe successively, a condition very like that in erythromelalgia. The gangrene spread upwards and amputation above the knee was subsequently performed. He appeared better for a while after this but the disease continued to progress in the other leg. Microscopic examination showed marked arterio-sclerosis in the tibial and pedal arteries of the amputated limb. Dr. Levy states that the most constant pathological findings in the few cases known were endarteritis and sclerosis of the smaller peripheral arteries with little or no neuritis.

THE NEW REGULATIONS FOR ADMISSION TO THE ROYAL ARMY MEDICAL CORPS.

ON p. 1339 will be found the text of the new regulations for admission to the Royal Army Medical Corps. They must, of course, be read in connexion with the recently published Royal Warrant for the Army Medical Service, the text of which was published in our issue of March 29th, p. 912. The new regulations both for admission to the Royal Army Medical Corps and for promotion when once admitted—for despite their title the regulations do not deal solely with admission—are obviously designed to attract the best class of man, and we hope for the sake of the service that this result will follow. The entrance examination is, it will be seen, of a thoroughly practical nature and one which any medical man who is duly qualified and who has attended diligently and with common-sense to five years' hospital practice should have no difficulty in passing. As, of course, it is a competitive examination the standard of knowledge required for admission to the service may vary a little from time to time, but it will never fall below a fairly high one. The examination before promotion to major, to be taken at any time after completing five years' service, is a purely professional one, for the surmounting of which it will be necessary for the candidate to keep his knowledge of medicine, surgery, hygiene, and bacteriology from getting rusty, while a good list of optional subjects will enable him to secure consideration for any special work that he may have done.

"THE CASE OF AN ELECTION."

IN our issue of April 6th, 1901, p. 1044, we published a letter from Dr. J. A. Shaw-Mackenzie detailing the somewhat extraordinary circumstances of his election to, and dismissal from, the post of physician to out-patients at the Samaritan Free Hospital for Women and Children. The facts are these: In September, 1900, the vacancy in the post of physician to out-patients was advertised, without any notification that the appointment when made would have to be confirmed. On Nov. 14th, 1900, the secretary wrote to Dr. Shaw-Mackenzie informing him that he had been elected. A like intimation was sent to the editors of the Medical Directory. Nothing was said about the appointment being provisional. Dr. Shaw-Mackenzie did the work of the post for a month, when he received an intimation from the secretary of the medical committee that the election was not confirmed and therefore that he need not attend as out-patient physician. On Dec. 21st the secretary of the hospital wrote to Dr. Shaw-Mackenzie that the election not being confirmed the post was vacant. On Jan. 23rd, 1901, he wrote that matters reverted to the *status* of Oct. 23rd, 1900, the date at which the report of the medical committee on the candidates was sent in. Eventually another medical man was appointed in place of Dr Shaw-Mackenzie and the latter gentleman has now received the following letter:—

---

[1] Intermittent Claudication, THE LANCET, June 22nd, 1901, p. 1773.

Samaritan Free Hospital for Women and Children,
Marylebone-road N W, April 16th 1902.

DEAR SIR,—The Committee of Management of the Samaritan Free Hospital understand that some misapprehension has arisen as to the circumstances attending your provisional appointment as honorary physician to the hospital and the subsequent election of another candidate The committee willingly state that your non-election, permanently, was not attributable to any fault or shortcoming on your part. You gave your valuable services to the hospital for some weeks and the committee had no reason whatever for dissatisfaction

The committee take this opportunity of expressing their regret that the letter to you, and the communication to the *Medical Directory* notifying your appointment, omitted to state that it was provisional only

I am, dear Sir, yours faithfully,
W GUNTRIP KING, Secretary.

To J A. Shaw-Mackenzie, Esq M D &c.,
31, Grosvenor-street, W

We are glad to see that "the committee take this opportunity," &c., but it seems odd they should have allowed 14 months to elapse before doing so

THE HEREDITY OF POETIC TALENT

IN a discussion opened at the Société Médico-Psychologique of Paris and reported in the *Archives de Neurologie* for April Dr P. Chaslin referred to the subject of the heredity of poetic talent, basing his remarks chiefly on a recent publication by Dr Möbius which dealt exhaustively with the same topic. Dr Chaslin and Dr. Möbius arrived at the following conclusions first, that great poetic talents were solitary and exceptional, even amongst persons exhibiting a taste or aptitude for poetry, secondly, that the mother of a poet was always an intellectually gifted woman, whereas the son of a stupid woman was always stupid; and, thirdly, that poetic talent was hereditary and was transmitted through the mother alone. Dr Chaslin cites numerous instances in support of these conclusions. It is not often that a great poet has left behind him reflections or observations bearing upon the origin of his special talent, but in this connexion we can cite the well-known instance of Goethe who made the confession that he inherited from his father his stature and seriousness but from his mother "a joyous nature and a turn for poetising."

ON THE EARLY SYMPTOMS AND DIAGNOSIS OF TABES DORSALIS.

AN interesting paper based on careful observation and study of 54 cases of tabes dorsalis, with special reference to early symptoms and diagnosis, is contributed by Dr D Fulton to the *Journal of Nervous and Mental Disease* for April last. Dr Fulton emphasises the importance of differential diagnosis from early general paralysis, a procedure which is by no means easy. Paræsthesiæ about the limbs and body were often the first symptoms in tabes dorsalis and they were observed in the early stages of the disease in 70 per cent. of cases In six cases difficulty in micturition was the first symptom and in four cases double vision was the initial symptom. Among the earliest symptoms of general paralysis, and antecedent to indications of insanity, there might be found loss of knee-jerk, Argyll Robertson pupil, "lightning pains," incoördination and weakness of the bladder, so that differentiation in these respects from tabes was impossible If, however, the characteristic clumsiness of speech and tremor of the tongue and lower facial muscles were present, general paralysis might be diagnosed to the exclusion of tabes. In reviewing the 54 cases it was surprising, says Dr Fulton, to note that a large proportion of patients (85 per cent.) gave a definite history of gastro-intestinal disturbance, such as "army diarrhœa," gastric and intestinal catarrh, chronic gastritis, chronic constipation, gastroptosis and enteroptosis, and chronic liver troubles, these having preceded the tabes by periods of time ranging from a few months to a few years. He thought that some obscure toxæmia of gastro-intestinal origin, combined with syphilis, constituted the exciting cause of tabes. Of the patients 52 were males and two were females Hereditary influences were rare; 54 per cent. of the cases gave histories of alcoholism or excessive smoking, 42 per cent. were obviously syphilitic, 11 per cent. had followed influenza, and in 4 per cent. the tabes had followed very shortly after typhoid fever, more than one cause being observed in the majority of cases. The general symptoms and their frequency were as follows loss of knee-jerks in 88 per cent. of the cases, Romberg's symptom (static ataxia) in 80 per cent, ataxic gait in 77 per cent., lightning pains in 73 per cent., paræsthesiæ in 70 per cent., Argyll-Robertson pupil in 67 per cent., incoördination in 65 per cent., vesical disturbances in 60 per cent., ocular paralyses in 27 per cent., and sexual weakness in 25 per cent. Other symptoms were less frequent. Treatment included extension, rest in bed with massage and passive movements, and, above all, hydrotherapy and systematic graduated exercises for the muscles so as to regain the power of coördination.

WHAT'S IN A NAME?

THE medical superintendent of one of the county asylums has had the courage to christen the institution of which he is the official head by a name suggestive of a residential estate with ancestral antecedents, thus discarding the old title of "asylum" with all its objectionable associations. There is much to be said in favour of this stroke of policy, and, indeed, the arguments against it are almost entirely of a technical nature. If the rich person who has to be confined under certificates can be lodged in a "park," "villa," or "moorings," why may not the poor man whose local habitation is paid for out of the rates be domiciled under a name with artistic associations? The law is not given to sentimentalism and it speaks in cold, brutal terms of institutions for the insane as "asylums, hospitals, or licensed houses." If, then, a "licensed house" may be generally known as "*Dottyville*," and so spoken of by the Lunacy Commissioners in their report to the Lord Chancellor, why may not the county asylum be known as "Muddleport"? There is plenty of scope for imagination in the new departure opened up by this enterprising superintendent, we would, however, suggest that the new styles should not be of too connotative a character, but that they should be rather colourless in kind, so that neither may the melancholy patients be made more depressed by the dismal name of their abode nor the general paralytics unduly elated by the "castle" that they have at last found. It has always been a sore point with the chief officers of asylums (and their wives) that they should be spoken of in the neighbourhood as "the asylum people" and that their residences should be part and parcel of the establishment and their letters so addressed that they very often fall into the hands of patients who happen to carry a similar name, and it is not to be wondered at that strenuous efforts are usually made to dissociate the quarters of the medical staff from the main structure and to give names which are bewildering to the postman, but there is now an example in actual existence where the hated word "asylum" disappears once and for all and life may be enjoyed in the most socially approved surroundings Seriously speaking, there is much to be said for this bold stroke, and if it does eventually relieve people from the prejudices which do undoubtedly, though often wrongfully, militate against the future of those who have had to spend some time in an asylum, the originator may be congratulated upon having initiated an advance.

THE DISTRIBUTION OF PLAGUE.

THE following shows the distribution of plague throughout Egypt during the week ending April 27th: Mit-Ghamr, 1 case and no deaths; Mit-Samanoud, 3 cases and no deaths; Dechneh, 3 cases and 2 deaths; Tala, 3 cases and 4 deaths; Tantah, 4 cases and 2 deaths; and Maghaga, 4 cases and no deaths. An outbreak of the disease has occurred among Bedouins living near the town of Maghaga (Upper Egypt). The first case traced was a Bedouin woman who left Korachieh in March.

SANITARY WORKS AT BUCKINGHAM PALACE.

THE drainage and other sanitary arrangements which were carried out at Buckingham Palace by the officials of His Majesty's Office of Works a few years ago have been thoroughly inspected and tested by Dr. W. H. Corfield, the consulting sanitary adviser to His Majesty's Office of Works, who has reported "that the drainage arrangements have been very well planned and carried out and reflect credit on all concerned with them." He has, however, suggested a number of improvements in the sanitary arrangements generally, the most important of which have been carried out already under his supervision and to his satisfaction. The remainder, which consist chiefly of certain rearrangements, will be carried out in the autumn.

THE METROPOLITAN WATER-SUPPLY.

THE report on the condition of the metropolitan water-supply during the month of March, 1902, has recently been issued by the Water Examiner. The Thames water was in good condition at Hampton, Molesey, and Sunbury from the 5th to the 16th and from the 19th to the 31st day of the month. On the 17th the engineer to the Chelsea Waterworks Company described the state of the river water as bad. The height of the river varied from three inches above to seven inches below the average summer level. The average daily supply delivered during the month was as follows: from the Thames, 111,171,611 gallons; from the Lee, 52,772,200 gallons; and from springs and wells, 36,001,249 gallons. The proportions of brown tint observed in a two-foot tube ranged from 5° to 24° of the standard in use. The water of the Lambeth Company exhibited the deepest average tint of brown and a sample of water drawn from the mains of that company was found (by Dr. T. E. Thorpe, F.R.S., the Government analyst) to contain a higher proportion of organic carbon than that found in any other sample of London water examined during the month. Dr. Thorpe examined 11 samples of the water supplied by each company during the period under review. Samples collected on March 17th were fully analysed. The most important results of this examination are given in the appended table showing the results of the analysis expressed in parts per 100,000.

Company.	Organic carbon.	Organic nitrogen.	Nitrogen as nitrates and nitrites	Total combined nitrogen.
Chelsea	0·205	0·017	0·270	0·287
West Middlesex .	0·205	0·018	0·260	0·287
Southwark	0·184	0·020	0·228	0·248
Grand Junction	0·246	0·023	0·259	0·282
Lambeth	0·249	0·021	0·271	0·292
New River	0·052	0·008	0·222	0·230
East London	0·236	0·019	0·445	0·464
Kent	0·041	0·006	0·466	0·472

THE PREVALENCE OF SMALL-POX.

THE returns of small-pox in London for the past week show the following figures. On Saturday, May 3rd, there were 38 fresh cases notified and removed; on Sunday, the 4th, there were 44 fresh cases; on Monday, the 5th, there were 40 fresh cases; on Tuesday, the 6th, there were 35 fresh cases; and on Wednesday, the 7th, there were 17 fresh cases. In the county of Essex for the week ending May 3rd there were notified 63 cases, making a total from Jan. 1st of 953 cases throughout the county. During the month of April 183 cases were notified in the Essex urban districts and 63 cases in the Essex rural districts.

AT a meeting of the Grand Lodge of English Freemasons held at Freemasons' Hall on Wednesday, April 30th, amongst the Grand Officers appointed for the ensuing year by the M. W. Grand Master, H.R.H. the Duke of Connaught, were W. Bro. A. E. Sansom, M.D., F.R.C.P. Lond., W. M. of the London Hospital Lodge, and W. Bro. Thomas Wakley, jun., L.R.C.P. Lond., W. M. of the Cheselden Lodge (St. Thomas's Hospital), who were appointed respectively to the offices of Senior Grand Deacon and Junior Grand Deacon.

THE annual dinner of the Indian Medical Service will take place at the Café Monico, Piccadilly-circus, on Thursday, June 12th, at 7.45 P.M., when the chair will be occupied by Dr. William S. Playfair. Officers intending to be present at the dinner should communicate without delay to the honorary secretary, Mr. P. J. Freyer, 46, Harley-street, London, W.

THE annual dinner of the Chelsea Clinical Society will be held in the Princes Room, Criterion Restaurant, on Thursday, May 22nd, at 7.45 for 8 P.M. Communications should be made to the honorary secretary, Dr. A. E. Cooper, 104, Buckingham Palace-road, London, S.W., not later than Thursday, May 15th.

THE ninth "Robert Boyle" Lecture of the Oxford University Junior Scientific Club will be delivered in the hall of Balliol College, Oxford, on May 13th, at 9 P.M., by Professor T. Clifford Allbutt of Cambridge, the subject being "The Growth of the Experimental Method in Oxford."

His Excellency the High Commissioner for South Africa has appointed Dr. Henry Shinglewood Taylor, Justice of the Peace, to be the commissioner for receiving the oath of allegiance to His Majesty King Edward VII. for the district of Ficksburg, Orange River Colony.

THE Committee of University College Hospital have decided not to hold this year the usual festival dinner in aid of the funds of the charity. They are, however, compelled to issue a special appeal for funds, the hospital owing a debt of over £9000.

THE forty-second annual dinner of King's College, London, will be held at the Monico Restaurant on Monday, June 16th, with the Bishop of London in the chair.

DR. J. E. WOLFHAGEN has been appointed Consul for Germany at Hobart, Tasmania.

WINDOW-WASHING APPARATUS.—An American inventor has patented a method of cleaning windows; it seems to consist of bars attached to the sides of the sash and a mechanical contrivance for causing a "window brush or cleaner" to travel over the surface of the glass. An engraving and the specification will be found in the *Official Gazette* of the United States Patent Office issued on April 22nd, 1902.

THE ROYAL ARMY MEDICAL CORPS.

THE following is the text of the new regulations for admission to the Royal Army Medical Corps.

[*Promulgated by Army Orders dated 1st May, 1902.*]

REGULATIONS FOR ADMISSION TO THE ROYAL ARMY MEDICAL CORPS, 1902.

CANDIDATES FOR COMMISSIONS.

QUALIFICATIONS.

1. A candidate for a commission in the Royal Army Medical Corps must be 21 years and not over 28 years of age at the date of the commencement of the entrance examination.

2. He must possess, under the Medical Acts in force in the United Kingdom at the time of his appointment, a registrable qualification to practise.

3. He must complete the form of application and declaration shown in Appendix I., and submit it to the Director-General, Army Medical Service, in sufficient time to permit of reference to the medical school in which the candidate completed his course as a medical student.

4 The Dean, or other responsible authority, of such school will be requested by the Director-General to render a confidential report as to his character, conduct, professional ability and fitness to hold a commission in the corps, and to this report special importance will be attached

5 After the form of application and the confidential report above alluded to have been received, the Director-General will decide if he may be allowed to compete for a commission in the Royal Army Medical Corps.

6. If approved, he will then be examined as to his physical fitness by a board of medical officers in accordance with Appendix II.

7. If the candidate is pronounced to be physically fit for service at home and abroad, he will be eligible to present himself at the entrance examination, which will be held twice in the year, usually in January and July, for the admission of qualified candidates as lieutenants on probation.

8. The Secretary of State reserves the right of rejecting any candidate who may show a deficiency in his general education.

9. An entrance fee of £1 is required from each candidate admitted to the examination and is payable at the conclusion of his physical examination if pronounced fit.

10. Officers who have served with the Royal Army Medical Corps (Militia) when embodied, or who as officers of the Royal Army Medical Corps (Militia) or Royal Army Medical Corps (Volunteers), medical officers of yeomanry or volunteers, or as civil surgeons served with an army in the field, after the 1st October, 1899, may be allowed to reckon such service towards retired pay and gratuity. [*Secretary of State's Instructions on Pay Warrant*.]

Candidates in any of these classes may be permitted to compete under the above rules provided they were not over 28 years of age at the beginning of their last period of service and shall be allotted special marks for such service on a scale approved by the Secretary of State. The duration of service is to be reckoned from the date on which the candidate commenced such service, except in the case of candidates who have served for two or more periods at short intervals. In such cases the total period of service to be considered in granting marks at the entrance examination shall be specially determined.

APPOINTMENTS, &c.

11. A candidate successful at the entrance examination will be appointed a lieutenant on probation, and will be required to pass through such courses of instruction as the Secretary of State shall decide, and after passing the examinations in the subjects taught, and satisfying the Director-General that he possesses the necessary skill, knowledge, and character for permanent appointment to the Royal Army Medical Corps, his commission as lieutenant will be confirmed The commission shall bear the date of the officer's appointment as lieutenant on probation.

12. Before the commission of a lieutenant on probation is confirmed he must be registered under the Medical Acts in force in the United Kingdom at the time of his appointment.

13. The precedence of lieutenants among each other shall be in order of merit as determined by the combined results of the entrance examination and the examinations undergone while on probation, except that the position on the list of a lieutenant on probation seconded under Article 349 Royal Warrant shall be determined by the place he has gained at the entrance examination. In the case of a lieutenant so seconded the subsequent examinations referred to in paragraphs 18 and 19 will be of a qualifying character and will not influence his position on the seniority list of the corps.

14. Lieutenants when appointed on probation will receive instructions as to the provision of uniform

EXAMINATIONS.

SUBJECTS FOR THE ENTRANCE EXAMINATION.

15. Candidates will be examined by the examining board in medicine and surgery. The examination will be of a clinical and practical character, partly written and partly oral, marks being allotted under the following scheme:—

Medicine (written).

	Maximum marks.
A. Examination and report upon a medical case in the wards of a hospital	125
B Commentary upon a case in medicine	125
(Three hours allowed for A and B together)	

Medicine (oral)

A. Clinical cases; clinical pathology	75
B. Morbid Anatomy and Morbid Histology	75
(One quarter of an hour allowed for each table.)	

Surgery (written).

A. Examination and report upon a surgical case in the wards of a hospital	125
B. Commentary upon a case in surgery	125
(Three hours allowed for A and B together.)	

Surgery (oral).

A Clinical cases, including diseases of the eye; surgical instruments and appliances	75
(One quarter of an hour allowed for this table.)	
B. Operative surgery and surgical anatomy	75
Total marks	800

The following headings are published as a guide to candidates in drawing up their reports on cases:—

(a) A brief history of the case as given by the patient, including such points only (if any) in the family or personal history as have a distinct bearing upon the present illness or incapacity.
(b) A detailed account of the subjective symptoms and physical signs elicited by the candidate's personal examination of the patient, noting the absence of any which might be expected to be present in a similar case.
(c) Where there is any reasonable doubt in the mind of the candidate as to an exact diagnosis, he is to give the alternatives, with his reasons for making the selection
(d) A commentary upon the case as a whole, pointing out the symptoms which may be considered typical and those which appear to be unusual or only accidental complications
(e) Suggestions as to treatment, both immediate and possibly necessary at a later date.
(f) A forecast of the progress and probable termination of the case.

Similarly the commentary on the report of a case submitted to the candidate should discuss:—

(a) The family and personal history and other conditions preceding the development of the condition described.
(b) The relative significance of the physical signs, symptoms, other indications of disease noted, and the general clinical aspects of the case.
(c) The diagnosis, with reasons for selection of the most probable, when a positive diagnosis cannot be attained
(d) The treatment, *dietetic*, medicinal, operative, &c., including a criticism of the plan adopted, and alternative schemes of treatment in cases of disagreement.
(e) The morbid appearances, and an account of the *post-mortem* examination (if any)

16. The examination will be held in London, and will occupy about four days.

17. The appointments announced for competition will be filled up from the list of qualified candidates arranged in the order of merit, as determined by the total number of marks each has obtained.

18. Having gained a place in this entrance examination, the successful candidates will undergo two months' instruction in hygiene and bacteriology, after which they will be examined in these subjects. The maximum number of marks obtainable at this examination will be 100

19. On completion of the above course lieutenants on probation will be ordered to proceed to the depôt of the Royal Army Medical Corps at Aldershot for a three months' course of instruction in the technical duties of the corps, and at the end of the course will be examined in the subjects taught The maximum number of marks obtainable at this examination will be 100

20. A lieutenant on probation who fails to qualify in either of these examinations will be allowed a second trial and should he qualify will be placed at the bottom of the list. Should he again fail in either examination his commission will not be confirmed.

REGULATIONS FOR THE EXAMINATION FOR PROMOTION IN THE ROYAL ARMY MEDICAL CORPS.

21 These examinations are intended to test the progress and proficiency of officers in those branches of knowledge which are essential to their continued efficiency

Lieutenant before Promotion to Captain

(For Lieutenants appointed after March 31st, 1901)

22. This examination may be taken at any time after completing 18 months' service and will be held in the military district in which the officer is serving

The subjects of this examination, which are detailed in the King's Regulations are as follows:—

1. Regimental duties.
2. Drill
3. Military law
4. Duties and accounts connected with military hospitals and their supplies
5. Other duties of executive medical officers.

Captains before Promotion to Major

(For captains promoted to that rank after July 27th, 1895.)

23. Captains will be examined under the rules laid down in Paragraph 24, and will be eligible for acceleration in their promotion to the rank of major under Article 352 of the Royal Warrant, subject to the following restrictions:—

(a) The acceleration which can be gained by a captain promoted to that rank in January 1896, will be limited to six months, and an officer gaining this acceleration will take precedence after the last captain promoted major on completion of twelve years' service.
(b) The acceleration which can be gained by a captain promoted to that rank in July, 1896, will similarly be limited to twelve months and an officer gaining this acceleration will take precedence next after the last captain promoted to that rank in January, 1896, who may have gained six months' service.
(c) A captain promoted to that rank in January, 1897, can gain the full acceleration but will take precedence after any captain promoted to that rank in July, 1896, who may have gained 12 months acceleration
(d) Officers gaining acceleration under (a) will take precedence inter se in order as they have obtained a special certificate or passed

in the first, second, or third class, and a similar course will be followed under (*b*) and (*c*).

(*e*) In all other cases an officer who gains accelerated promotion will be placed for precedence after the last officer (whether subject to acceleration or not) promoted approximately, three, six, 12, *or* 18 *months* before him.

24. This examination, which may be taken at any time after completing five years' service, will be held in London on the termination of a *period of special study. The examination* will consist of written papers, essays, oral and practical examinations in the following subjects, which are detailed in the King's Regulations:—

1. *Medicine.*
2. Surgery.
3. Hygiene.
4. *Bacteriology* and *tropical* diseases.
5. One special subject from the subjoined list, to which additions may from time to time be made:—(*a*) Bacteriology, including the preparation of antitoxins; (*b*) dental surgery; (*c*) dermatology; (*d*) laryngology; (*e*) midwifery and gynæcology; (*f*) operative surgery, advanced; (*g*) ophthalmology; (*h*) otology; (*i*) pædiatrics (*k*) psychological medicine; (*l*) skiagraphy; (*m*) specific fevers.

25. Captains serving in that rank before July 27th, 1895, will be promoted under the old regulations contained in Appendix I., Regulations for Army Medical Services, and will not be eligible for acceleration.

Majors before Promotion to Lieutenant-Colonel.

(For majors promoted to the rank after March 31st, 1895.)

26. This examination, which may be taken at any time after three years in the rank of major, will be held in the military district in which the officer is serving at times which will be duly notified.

The subjects of this examination, which are detailed in the King's Regulations, are as follows:—

1. Military law.
2. Army medical organisation.
3. Sanitation of towns, camps, transports, &c.
4. Epidemiology and the management of epidemics.
5. One special subject from the subjoined list to which additions may from time to time be made:—
   (*a*) Medical history of important campaigns.
   (*b*) A general knowledge of the army medical services of other Powers.
   (*c*) The laws and customs of war in relation to the sick and wounded.

APPENDIX I.

APPLICATION OF A CANDIDATE FOR A COMMISSION IN THE ROYAL ARMY MEDICAL CORPS.

1. Name in full.
2. Address.
3. Date of birth.

(A certificate of registration of birth or other satisfactory evidence of age, such as a declaration made before a magistrate by one of his parents or guardians giving the date of his birth to be furnished.)

4. Registrable qualifications.

(A *reference to be given to the* Medical Register, or, in the absence of such *reference, other satisfactory* evidence to be furnished.)

5. Academic and other distinctions.
6. Name of the Dean or other responsible *authority of the* school in which the candidate *completed* his course as a medical student.
7. Particulars of any commission or appointment held in the public services.
8. Date *of* examination at which the candidate proposes to present himself.

DECLARATION.

(*N.B.*—A mis-statement by the candidate will invalidate any subsequent appointment and cause forfeiture of all privileges for services rendered.)

I hereby declare upon my honour that the above statements are true to the best of my knowledge and belief, and that I am a British subject of unmixed European blood.

(Signed)

A candidate whose application is regarded as satisfactory will be directed to appear before the Director-General, Army Medical Service, usually on the fourth Thursday of the month preceding his examination. If allowed to compete he will be required, a few days before the examination, to present himself before a medical board to be certified as to physical fitness. He will be informed in due course of the time and place at which such board will be assembled.

All communications to be addressed to the Director-General, Army Medical Service, 18, Victoria-street, London, S.W.

REVISED CLASSIFICATION OF CAUSES OF DEATH IN THE NATIONAL RECORDS.

IN THE LANCET of April 26th, p. 1196, we briefly acknowledged our indebtedness to the Registrar-General for a copy of the new official list of causes of death which was adopted at the beginning of the present century for the abstraction of deaths in England and Wales. Except for a few unimportant modifications the classification which has now been superseded is identical with that which had been in use at the General Register Office ever since its establishment in 1837. It was compiled by the late Dr. William Farr, F.R.S., shortly after his appointment to the office which he made illustrious throughout his long period of faithful service. And although we can readily believe that the classification which it embodied requires modification at the present time it is beyond question that in earlier years at any rate Dr. Farr's classification effected substantial improvement in the records of mortality not only in this country but in most other parts of the civilised world.

The new list of causes of death which we print *in extenso* is obviously the work of Dr. John Tatham who, as a member of the committee of the Royal College of Physicians of London which prepared the last edition of the Nomenclature of Diseases, is presumably familiar with the views of his professional colleagues at Pall Mall on the subject of classification. And, further, we believe, from the great interest which he has always shown in the progress of State Medicine and especially in the science of Vital Statistics, that any serious departure from the methods of his distinguished predecessor would have been decided upon by Dr. Tatham only after the most painstaking and mature reflection.

Although, as we mentioned in our issue of April 26th, the time-honoured grouping of diseases by Dr. Farr under the titles "Zymotic," "Constitutional," "Developmental," &c., will be missed in the new list, nevertheless, inasmuch as the names of groups only, not the names of diseases themselves, have been discontinued, it will be found on examination that the instances are few and unimportant in which the records of future years cannot readily be compared with those of the past.

Attached to the new list of causes of death are a few appropriate suggestions for its use. We commend these to the careful perusal of our medical brethren who will find them helpful in regard to the certification of cause of death. We are glad to note that copies both of the new official list of causes of death and of the suggestions referred to will be included in all future books of certificate forms issued from the General Register Office. Consequently these documents will be at hand just when they are most useful to the medical practitioner—namely, at the very time of filling up his certificates.

We are gratified to find on inquiry that the new list of causes of death has been adopted by the Registrars-General for Ireland and Scotland, so that uniform official statistics of mortality will henceforth be published for the three divisions of the United Kingdom.

NEW LIST OF CAUSES OF DEATH

AS USED IN THE ANNUAL REPORTS OF THE REGISTRAR-GENERAL FOR ENGLAND AND WALES.

N.B.—The terms printed in *italics* being the names of symptoms merely, or being otherwise objectionable, should be used in medical certificates only when precise information is wanting.

SUGGESTIONS TO MEDICAL PRACTITIONERS RESPECTING CERTIFICATES OF DEATH.

It is highly desirable that medical practitioners should use in their certificates of death only those terms which are recognised by the Royal College of Physicians

> The list of diseases now used in the Registrar General's Reports is condensed from the nomenclature of the Royal College of Physicians, with the addition of certain unofficial terms which are still in common use but which are objectionable either as being the names of symptoms merely or as being otherwise indefinite. In the copy of the list here given those objectionable terms are printed in *italics*, and it is hoped that medical practitioners will use them only when accurate information is wanting.

1. The cause of death should be stated precisely and briefly, English names for diseases being used in preference to their equivalents in other languages. Vague terms such as *decline, consumption, tabes cachexia*, &c., should be avoided, and *hæmorrhage* should not be assigned as the cause of death without indication of its origin and probable cause. *Dropsy* should never be returned as the cause of death without particulars as to its probable origin—e g., in disease of the heart, liver, kidneys, &c.

2. SMALL-POX.—In certifying deaths from small pox the patient's condition with respect to vaccination should be carefully stated—say, in one or other of the following forms:—(1) No evidence of vaccination. (2) Vaccinated in infancy only—Number of scars. (3) Vaccinated only after infection from small pox. (4) Stated to have been vaccinated but no scars. [If the patient has been revaccinated, the date should be given when possible.]

3 PUERPERAL FEVER AND OTHER SEPTIC DISEASES.—The term "*puerperal fever*" should no longer be used. Pyæmia, septicæmia, or sapræmia occurring in puerperal women should be described as puerperal pyæmia, puerperal septicæmia, or puerperal sapræmia respectively (Nomen. R.C.P., p. 11). In the new list of diseases provision exists for the separate entry of the several forms of septic infection.

4. DIARRHŒA.—Attention is especially invited to the subjoined decision of the Royal College of Physicians concerning the use of authorised names for this malady dated Jan. 25th, 1900.

"The Royal College of Physicians is convinced, after careful inquiry: (a) That various unauthorised and misleading terms, such as '*gastro-enteritis*,' '*muco-enteritis*,' '*gastric catarrh*' &c., are now commonly employed to designate the disease officially known as '*epidemic diarrhœa*,' whereby its specific character is in danger of being ignored, and great confusion ensues. (b) that the present confusion of terms renders it impossible to determine accurately either the prevalence of the disease in special places and at special times, the extent to which it influences the public health, or the effects produced by sanitary measures; (c) that there is a widespread objection on the part of medical practitioners to the employment of the term '*diarrhœa*' in certifying the cause of death, probably because that term is generally held by the public to imply a mild disease, insufficient by itself to cause death

"The College, therefore, has sought to discover as an alternative for the authorised term (epidemic diarrhœa) some other name, which, whilst equally accurate, should convey to the public the idea of a more serious affection. But the College regards it as essential that the idea of specificity, intended to be conveyed by the term 'epidemic,' should be retained.

"As the result of much deliberation, the College has agreed to authorise the use of the term '*epidemic enteritis*' (or if preferred by the practitioner, '*zymotic enteritis*'), as a synonym for epidemic diarrhœa. The College has further decided to urge upon practitioners the entire disuse, in medical certificates of death, of such terms as '*gastro-enteritis*,' '*muco-enteritis*,' or '*gastric catarrh*,' as synonyms of epidemic diarrhœa."

5. MALIGNANT DISEASES.—Among cancerous affections "carcinoma" is now distinguished from "sarcoma." This distinction should be observed wherever possible. A separate line is, however, still retained for those forms of malignant disease the nature of which cannot be specified precisely. The part of the body affected should always be stated in the certificate

6 TUBERCULOUS DISEASES. "*Phthisis.*"—When this condition is due to tubercle, the term "tuberculous phthisis" or "pulmonary tuberculosis" should be used instead of the ambiguous term *phthisis*, which is sometimes used to designate other besides tuberculous diseases of the lungs. "*Tabes mesenterica*"—The use of this term to describe tuberculous disease of the peritoneum should be discontinued, as it is frequently used to denote various other wasting diseases which are not tuberculous. "Tuberculous peritonitis" is the better term to employ when the condition is due to tubercle. *Hydrocephalus*.—In certifying deaths thus caused it would be advantageous if those due to tuberculous infection were distinguished from those due to meningitis or to other affections of the brain. "Congenital hydrocephalus" should always be returned as such.

7 CONVULSIONS.—It is hoped that this indefinite term will henceforth be restricted to those cases in which the true cause of convulsions cannot be ascertained. At present more than 11 per cent. of the total deaths of infants under one year old are referred to "*convulsions*" simply.

8. PARALYSIS.—The classification of deaths would be much facilitated if brain paralysis were always distinguished from paraplegia. In certifying deaths from brain paralysis, the terms "*hemiplegia*" and "*apoplexy*," which denote symptoms merely, might usefully be replaced by the names of such definite lesions as "cerebral hæmorrhage," &c., &c.

9. PNEUMONIA.—Three separate forms of acute pneumonia have now been added to the list—viz.: Croupous or lobar pneumonia, broncho, catarrhal, or lobular pneumonia, and epidemic pneumonia, the old line for undefined cases of pneumonia being still retained. The term "*typhoid pneumonia*" should never be employed, as it may mean either enteric fever, with pulmonary complication, on the one hand, or pneumonia, with so-called typhoid symptoms, on the other.

10 CROUP.—It were greatly to be wished that the use of the term "*croup*" to designate non-diphtheric affections of the larynx or trachea should be abandoned. Diphtheritic croup or membranous croup should be returned as such.

11 CHILDBIRTH.—Whenever parturition or miscarriage has occurred within one month before the death of the patient the fact should be certified, even though childbirth may not have contributed to the fatal issue

12. VIOLENCE.—In every case of death by violence, or by suspected violence, the medical practitioner, in addition to stating the fact in his certificate, should advise the friends of the deceased to inform the coroner forthwith

13. When the cause of death has been verified by a post mortem examination the letters P.M. should be added

---

HEALTH OF KEYNSHAM RURAL DISTRICT.—Mr. J. O. Heaven, the medical officer of health, in his annual report for 1901 estimates the population at 8295, the area being 21,406 acres. 114 deaths were registered during the year against 120 in 1900, corresponding to a rate of 13·74 per 1000. 173 births were registered, compared with 101 in 1900, equal to 20·85 per 1000 living.

DONATIONS AND BEQUESTS.—By the will of Mr. Thomas James of Aylmer House, Weston-super-Mare, and of Messrs. Stiff and Co., Limited, starch manufacturers, of Bristol, £100 are bequeathed to the Weston-super-Mare Hospital and £50 to the Weston-super-Mare Convalescent Home for Children.—The late Mrs. Stephen Wilson of North Kinmundy has bequeathed £1000 to the Royal Hospital for Sick Children, Aberdeen, for the endowment of a cot to be named the "Stephen Wilson Memorial Cot."—The Court of Directors of the Bank of England have granted a donation of £100 to the funds of the Middlesex Hospital in response to the appeal which the governors made for the sum of £70,000.—By the will of Miss Eleanor Agnes Carr £200 are bequeathed to the Alnwick Infirmary.—Captain John Borlase Tibbits by his will has bequeathed £100 to the Northampton Infirmary.

TESTS OF DOMESTIC OPEN FIRE-GRATES.

WE publish below the account of a preliminary investigation into the subject of open sitting-room fire-grates, which has been undertaken at the instance of the Coal Smoke Abatement Society by Dr. H. A. Des Vœux and the late Mr. Bryan Donkin, C.E. The medical and sanitary world have had, since the writing of the report, to regret the death of Mr. Donkin, whose practical and scientific experience in this and allied subjects was probably greater than that of any other observer in the kingdom.

When in 1899 the Coal Smoke Abatement Society was formed to grapple with the problem of the pollution of the air of London with smoke, it soon found itself engaged in a conflict with an enemy which had remained supreme for over 500 years. On the first introduction of coal into London there was some opposition to its use in the City as being prejudicial to the health of the inhabitants, but its undisputed value and the impossibility of finding an efficient substitute soon left coal in possession of a field where there were no serious rivals. Its use, however, was at first limited; it was a luxury and therefore could only be enjoyed by a few; and the damage then done by smoke was small compared with that occasioned in modern times. This increased damage is owing to the ever-increasing use of coal among a population which is in itself rapidly augmenting, not only in numbers, but also in wealth. An increased population with an increased wealth per head means a vastly greater spending power on the luxuries of life; and warmth in the home is one of the first luxuries which comfort demands. The enormous advances which have been made in manufacturing by machinery during the last hundred years have caused the opening of an ever-increasing number of factories and mills, and therefore the demand for coal "to produce steam" has grown *pari passu* with its increased use on the domestic hearth.

In 1819 the attention of Parliament was directed to the question of the nuisance created by coal smoke and a Select Committee was appointed "to inquire how far persons using steam-engines and furnaces could erect them in a manner less prejudicial to public health and comfort." This committee gave an encouraging report. In 1843 another Select Committee recommended the introduction of a Bill prohibiting the production of smoke from furnaces and steam-engines. In 1845 yet another Select Committee reported that such an Act could not, *in the existing state of affairs*, be made to apply to dwelling-houses. The Acts of 1845 and 1847 followed as the results of these inquiries. But it was not until 1875 that there was any effective legislation on the subject, when the Public Health Act, 38 & 39 Vict., was passed, cap. 55, Part III., sec. 91, paragraph 7 of which enacts as follow:—

> Any fireplace or furnace which does not as far as practicable consume the smoke arising from the combustible used therein, and which is used for working engines by steam, or in any mill, factory, dye-house, brewery, bakehouse, or gaswork, or in any manufacturing or trade process whatsoever; and any chimney (not being the chimney of a private dwelling-house) sending forth black smoke in such quantity as to be a nuisance, shall be deemed to be nuisances liable to be dealt with summarily in manner provided by this Act: Provided, secondly, that where a person is summoned before any court in respect of a nuisance arising from a fireplace or furnace which does not consume the smoke arising from the combustible used in such fireplace or furnace, the court shall hold that no nuisance is created within the meaning of this Act, and dismiss the complaint, if it is satisfied that such fireplace or furnace is constructed in such manner as to consume as far as practicable, having regard to the nature of the manufacture or trade, all smoke arising therefrom, and that such fireplace or furnace has been carefully attended to by the person having the charge thereof.

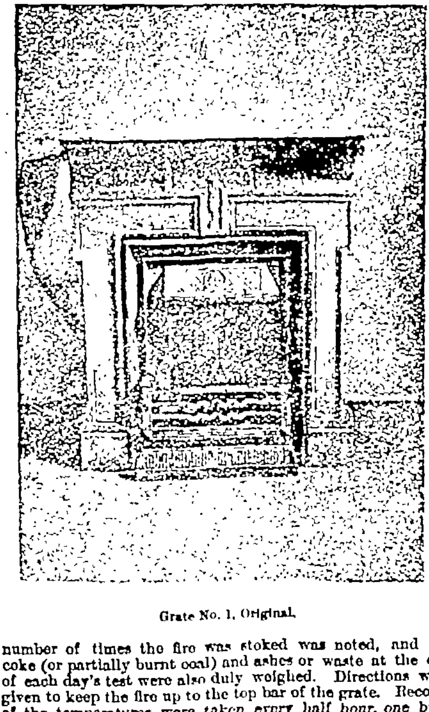
This Act of Parliament still holds good for the country but for London another Public Health Act was passed which contained almost the same clauses as that of 1875 but transferred the power to act thereunder from the police to the local authorities. For various reasons this Act was allowed to fall into abeyance, and when the committee of the Coal Smoke Abatement Society first commenced operations its lines of procedure naturally lay in two directions—viz., first, to impress upon the local authorities the importance of enforcing their powers under the Act of Parliament; and secondly, to study the question of the pollution of the atmosphere by smoke from domestic fires. The first line has been continuously followed up with great success and it is pleasing to note that many of the authorities are now exercising their powers in a satisfactory manner. The society hopes that in another year or two their work in that direction will perhaps come to an end. But the second project is even more important though little progress has up to the present been made with it. There are various causes for this. In the first place, many persons have asserted that if the smoke emitted from factory chimneys were stopped the amount from private chimneys would not be sufficient to cause much harm in London and other large cities and towns. In the second place, the society had to contend against the apathy born of the custom of centuries and the inherent conservatism of the English people who, despite their dislike to "dirt," seemed quite prepared to put up with it if the price of cleanliness were the abolition of their coal fires. Another difficulty was experienced in refuting the false idea that the smoke in the atmosphere was one of the causes of the general healthiness of London. This sophistry has probably arisen from the analogy of the carbon filter—i.e., if carbon purifies water, why should it not purify air?

But opinion is changing steadily; more people are becoming interested in the question of smoke abatement and it is very likely that in the next few years we shall see not London only but all large towns demanding that something shall be done to diminish smoke. The society has been consulted many times as to the best method of abolishing smoke not only by the users of domestic grates but also by manufacturers using steam boilers and furnaces. Up to the present it has refused to give any counsel on this question, as it was not in a position to advise upon the many devices now employed with success in factories. It had no expert experience or knowledge as to boiler furnaces and it therefore refrained from pretending to be wise. Moreover, there existed expert engineers on this subject and the society considered that they were the persons to be consulted thereon. But on the subject of domestic grates there were no experts and although there exists an abundance of specifications and drawings of improved grates and appliances connected therewith no large manufacturer of grates has thought it worth his while to study the question of a smokeless grate, the manufacturers' idea appearing to be that there is "no money in it"—i.e., no demand on the part of the public for a type of grate which diminishes the emission of smoke. The society therefore stepped into the breach and authorised a subcommittee to institute a series of tests on a few domestic grates. Before describing these it is well to premise that the Coal Smoke Abatement Society is fully aware that the object it principally aims at—viz., smokelessness—can be attained by the use of smokeless fuels, such as anthracite coal, coke, gas, or oil. Any one who is interested in the question can coöperate by using at least one of those fuels and he may rest satisfied that he is contributing his part to remove one of the greatest evils from which London and all coal-burning cities suffer. Fortunately, too, each of these fuels in its different degree is within reach of everybody; but, as it appears that the great majority of householders are at present unwilling to accept anything but open grates burning smoky coal, the society has confined its tests to grates claiming more or less to be smokeless under such conditions.

In order to secure the most comprehensive results the society inserted in two London newspapers—viz., the *Daily Telegraph* and the *Daily Mail*—advertisements calling the attention of manufacturers to the tests which they proposed to make. To these advertisements a large number of replies were received, describing various grates the majority of which, however, did not fall within the specified limits—viz., an open grate burning smoky coal. A certain number therefore had to be selected, the specifications of which showed them to be such as the society was seeking, and the manufacturers of these selected grates were invited to send samples to be tested. Six only responded to the invitation and were willing to have the tests made by the society and to have the results published. In the meanwhile Lord Esher, C.B., Secretary to the Commissioners of His Majesty's Office of Works and Public Buildings, had expressed a strong interest in what the society was undertaking, and finally he offered to place at its disposal a room in which the tests could be properly instituted and the services of two skilled employés to conduct them. The assistance of the Government at such a moment was, of course, invaluable, as it ensured the tests being conducted in such a manner that each grate could be judged absolutely upon its merits. It was especially unfortunate in view of the exceptional opportunities afforded by the Government that more manufacturers did not compete. Since so few came forward with suitable grates the results cannot be regarded as comprehensive. It cannot be for a moment asserted that the best open grate in the market has been discovered. All that can be claimed is that certain preliminary results of the highest importance have been obtained and that it has been shown to be capable of proof that there is a great difference in effectiveness and economy between the various types of so-called smokeless grates and that it is possible to produce them so as to reduce smoke pollution from domestic chimneys to a great extent while still using ordinary coal and an open grate.

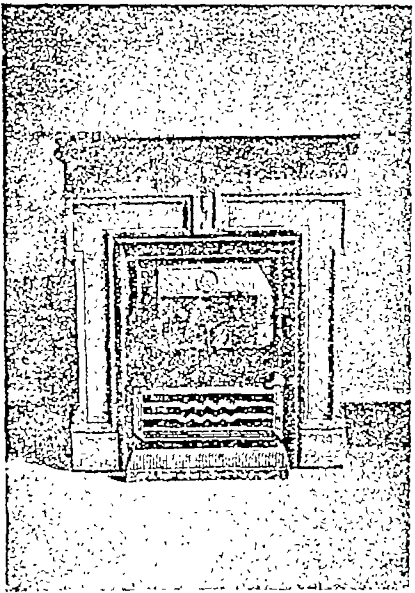
The following is a general description of the circumstances in which the tests were made. A sitting-room on a ground floor in central London was selected, 21 feet 6 inches by 14 feet 6 inches by 10 feet 6 inches. Its two glass windows were always kept shut, but a small glass ventilator in one window was continually open, as was also a door leading to a narrow hall. The street door was whenever possible kept shut. The chimney measured 69 feet from hearth to pot, with a nine-inch pot on a flue 14 inches by nine inches. No high buildings were situated near. The tests were made in the months of June, July, and August, 1901. The meteorological observations for the days of the tests were noted and are added in an appendix. Each grate was placed in position by the maker's fixer with the intention of testing it for three days of eight hours each. The manufacturer's directions were given either verbally or in print to the man whose duty it was to attend to and to stoke the fire and to note the temperature of the room. The following orders of the sub-committee were observed. The amount of wood used in lighting and the amount of coal put on each time throughout the day were ascertained by weight, the number of times the fire was stoked was noted, and the coke (or partially burnt coal) and ashes or waste at the end of each day's test were also duly weighed. Directions were given to keep the fire up to the top bar of the grate. Records of the temperatures were taken every half hour, one by a thermometer six feet from the fire and two feet above the floor level in order to give approximately the radiant heat; another at the far end of the room away from the window and the door, and five feet off the ground; and a third in the hall outside the room. The amount of smoke emitted was recorded by means of a smoke intensity scale or "smoke-shade," as indicating the proportion of unburnt carbon, on a time smoke chart (Bryan Donkin). It was estimated by a skilled man sitting in a window on the third floor of the opposite house at an angle of about 30° from the top chimney and about 35 feet away. He was watching during the whole working day continuously without going away for meals. Every precaution was taken to avoid error and each grate was tested in exactly the same way. The coal was ordinary household bituminous smoky coal of rather poor soft quality and was all taken from one truck, the name of the colliery being unknown.

FIG. 1.



Grate No. 1, Original.

FIG. 2.



Grate No. 1a, Original with regulator. (We have omitted the plotted diagram of degrees of intensity of smoke on a time basis (see p. 1345) with reference to this grate.—ED. L.)

The following are the possible sources of error—the summer weather, the variation in outside conditions of atmosphere (although, as will be seen upon reference to the meteorological reports, the weather differed little throughout), and, finally, the fact that orders were given to keep a bright fire up to the level of the top bar, whereas in an ordinary room the fire is often allowed to become extinguished or to fall low, when it has to be relighted or carefully stoked. With all of the grates the densest smoke was noticed immediately after stoking. It would have been better to have made tests during winter.

Six grates were tested, each for three days, in addition to the one which had been in use in the room previously, which being rather old-fashioned was taken as a standard and noted as No. 1.

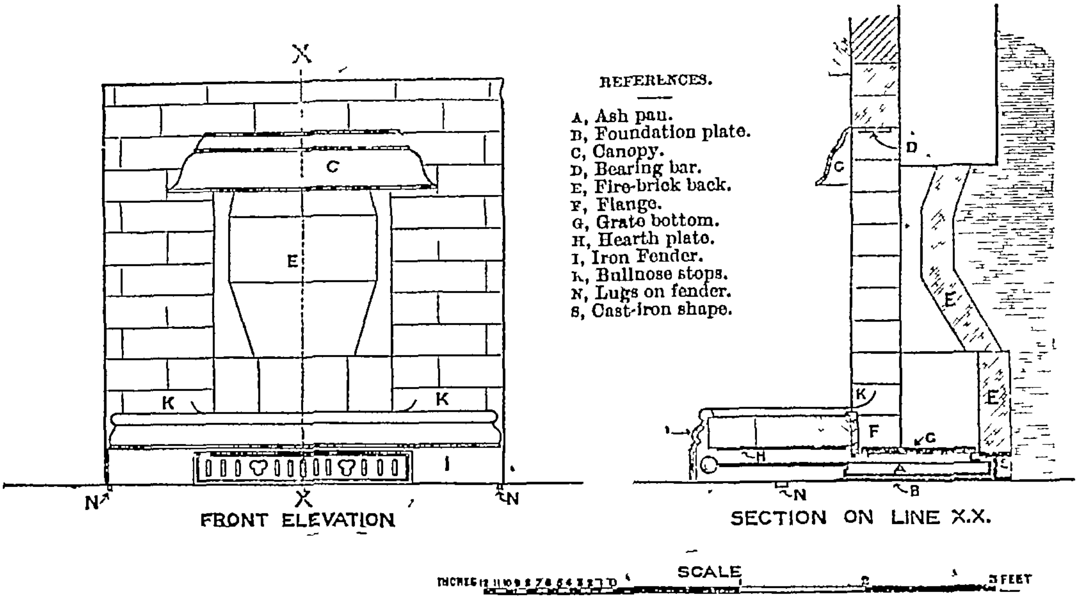
Grate No. 1.—The following is a description of this grate. Fire-brick back with iron sides, three horizontal bars in front. The bottom of the grid was formed of horizontal iron bars with alternate air spaces, and was about four inches above the hearth level. (*Vide* Fig. 1 and Chart 1.)

The daily consumption of coal was 28,[1] 30½, and 32 pounds.

---

[1] The 28 pounds represent the coal consumed between the hours of 10 A.M. and 5 P.M.; the other two amounts that consumed between the hours of 9 A.M. and 5 P.M.

FIG. 3.



Details of construction of Teale's patent front hob fire-place.

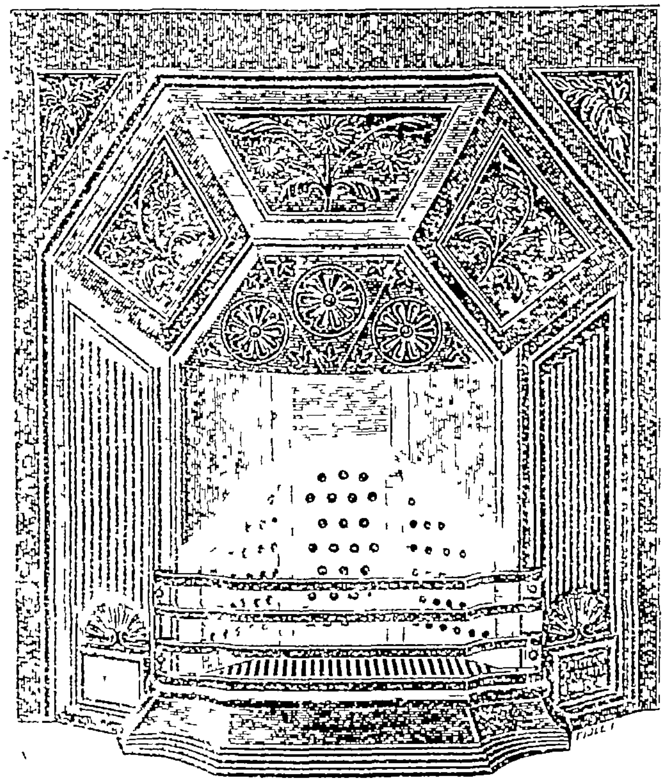
respectively; the amount of incompletely burnt coal left, three pounds, one and a half pounds, and three pounds; and the amount of ashes three and a half, one and a half, and three and a half pounds. The average daily differences in temperature between the outside thermometer and the radiant heat thermometer were 18·6°, 24·0°, and 26·24° F. The average time taken in raising the temperature from the morning scale to its average height was two hours, one and a half hours, and one hour respectively. The average number of times it was stoked (per day) for the three days was nine or ten times.

Grate No. 1a.—This was No. 1 grate with Lee's regulator added. This regulator is described as "a blower fitted with a damper. ...... It controls the supply of air to the grates and provides the proper velocity up the chimney." "The blower is joined to the regulator or damper at its lower edge by a hinge and is worked by means of a quadrant rachet." (Fig. 2.) The result of adding the regulator was as follows. The daily consumption of coal was 44, 33½, and 29 pounds respectively; the amount of incompletely burnt coal was two pounds per day; and the amount of ashes two pounds per day. It was stoked between 10 and 11 times each day. The average differences in range of temperature were 29·29°, 22·06°, and 20·29° F.; the time taken to raise the temperature of the room to its mean temperature was one and a half hours, one hour, and one hour respectively. [N.B.—This is the only appliance of which the testing exhibited somewhat contradictory results on each of the three days, and it is possible that some source of error was introduced which escaped notice. It gave the greatest heat with the greatest consumption of coal on the first day. This cannot be accounted for by the only known source of error—namely, that the chimney was not swept before its use. It was swept after and there was not much soot found.] The chimney smoked badly throughout independently of the amount of coal burnt.

Grate No. 2.—Teale's Patent "Front Hob" Fireplace (*Vide* Fig. 3 and Chart 2.) This grate is constructed almost entirely of firebrick with a hot-air chamber below the fire which burns in a hollow or well. It is manufactured by the Teale Fireplace Company and is described by them as being of their standard pattern and the smallest size they make—viz., 13 inches. The bricks are salt-glaze. It has a canopy, a firebrick back and sides, and a cast-iron bottom or grid. It burnt 28, 28, and 23 pounds of coal on the respective days and left two, two and a half, and two pounds of partially consumed coal, and two, two, and one and a half pounds of ashes. Its heat production for the three days was 20·17°, 20·88°, and 18·47° F. respectively. One hour each day was occupied in producing this average heat and the grate was stoked between five and six times each day.

Grate No. 3.—Helyear's Patent "Tropic" Grate. This grate has no register and is entirely closed on the top. It possesses a canopy, a cast-iron back, and hexagonal projecting cast-iron sides consisting of flues down which the heated gases pass on their way to the chimney. The lower portions of the back and sides are covered by a lining of cast-iron perforated plates or cheeks. The front consists of three horizontal iron bars and the bottom or grid of horizontal iron bars. (*Vide* Fig. 4 and Chart 3.) It burnt 23, 23, and 22 pounds of coal in the three days respectively, left one pound of

FIG. 4.



Grate No. 3. Helyear's patent "Tropic" grate.

the usual fittings used for this purpose and their installation would undoubtedly provide a most sanitary method of storing water and of using it both for drinking and flushing purposes. The disadvantages to the system are its cost and the great weight of the storage cistern. Everything would require to be made particularly strong to withstand the pressure of the main supply which, as we have said, in many instances is great. It is only fair to add that the fittings are beautifully made and are of first-rate material. We have inspected an installation which we found to be working most satisfactorily.

AN IMPROVED CISTERN.

IT is desirable that the cistern containing the water-supply for domestic use should be as free as possible from projections on which dirt and decomposing matter can easily accumulate. As a rule, the average cistern presents rivets and other projections which are favourable to the deposit of dirt in the storage tank. In order to remove this real objection Mr. T. B. Leech (of the Blackwall Galvanised Iron Co., Limited) has designed a steel-welted cistern with a uniform surface and with no projecting rivets. Moreover, the corners at the bottom of the cistern are filled in with triangular sheets of metal slanting downwards. The whole surface is carefully galvanised. The cistern may be commended since its object is to maintain the cleanliness of the domestic water-supply.

ASYLUM-SHYNESS.

(FROM A CORRESPONDENT.)

IT is now so well established that insanity may result from disease of any organ of the body and that it is not necessarily dependent on primary affection of the brain and nervous system that there is difficulty in understanding the rooted objection in the upper classes to placing people in private asylums or hospitals, where at any rate there is some amount of official supervision, whilst they do not hesitate to put them in "homes" which are in no way supervised and which may or may not be carried on in the most unexceptionable manner. To account for this the general notion of hereditary taint has much to answer for. It seems to be thought that because a person has been placed in an institution for the insane the offspring of necessity is tainted with an opprobrious history which handicaps them in the race of life. That such a dread of the very name of an asylum does exist cannot be denied, but it is a most unreasonable idea to hold, and the result is that another form of imprisonment is substituted for the comparative freedom of the hospital for the insane. If it were generally accepted, as it ought to be, that insanity due to the direct hereditary transmission of primary disease of the nervous system is by no means common and that the "asylum" is merely a place where the nervous symptoms due to general disease are treated there should be no more objection to acknowledging that a friend or relative has been treated in such a hospital than there is in saying that he has been ill in bed from jaundice or pneumonia. It cannot be denied that insanity is in some instances distinctly hereditary—and if so, what is the use of trying to burke the fact and so to establish an entirely false relationship of the individual to the community? —but very often the fact of having had an insane progenitor is not of the least consequence *quâ* the sanity of the offspring, and it is only ignorance that makes people speak in bated breath of the fact of somebody's wife or husband having been placed under certificates. That an individual has never been in an asylum does not prove his sanity—it merely shows that he has not been certified to be insane and it leaves the task of finding out a neurosis to those whose concern it may be. Do those who for matrimonial, business, or other purposes inquire if a person has at one time been in an asylum ask if he or she has ever been placed in a "home," and do they recognise that these "homes" are often asylums without the name, but with possibly harsh and at times cruel conditions? There are numbers of places where people suffering from nervous and early insane states are confined, without external supervision, under restrictions of enforced stay in bed, of complete isolation from their friends and from the external world, where they can neither see the newspapers nor communicate with their relatives—where they are, in fact, confined as in asylums without the security of the latter, and where they are subjected to systems of treatment which they have not the power to resist. Such isolated treatment is not necessarily wrong—it may be quite beneficial to a person to be kept in bed, stuffed with milk, and made to "gain weight" like a Strasburg goose—but it represents also a possible source of restraint to which people may be subjected, and there seems to be no law of registration or any guarantee that persons so detained can leave these places when they choose, or that they may not be placed in them by interested persons without any certificate or warrant. This system of to-day has arisen chiefly from the dislike of people to have it known that their relatives have ever been in an asylum, whereas if it were made clear that insanity in the parents does not of necessity connote insanity in the offspring, and that very often insanity on one side or the other is an accidental symptom of no meaning at all as regards hereditary transmission—if this true view were better known there would be less hesitation in responsible persons to allow the treatment of their friends or relatives in properly inspected institutions. Although there is no reason to think that patients are unduly detained in private asylums, it would be much more satisfactory to the public if the owners of these institutions, who are generally the people responsible for the medical treatment of their patients, were to annex to their staff some independent medical man. The medical owners of private asylums are invariably courteous and they give the most free access to the visits of any medical man deputed by the friends to visit an inmate, but the public should understand that there is no stigma in having their relatives in an asylum or hospital for the insane; and this better appreciation might be aided by the appointment of some general and well-established medical man in the neighbourhood who would form a link between the disease of the general hospital and that of the special one. It seems hopeless to expect that in the lower classes the stigma of having been treated in an asylum will ever be eradicated, because employers of labour are very suspicious of having in their midst anyone who is known to have been at any time placed in such conditions, and thus it comes about that the stigma of insanity means starvation; but the better classes are, or should be, too well informed to be ignorant of the fact that hereditary taint is very wrongly interpreted in the majority of cases, and that any attempt to elude the laws drawn up for the protection of persons in public or private retreats is sure to result in a form of seclusion which may be all the worse because it is secretly enforced.

NOTIFICATION OF PHTHISIS AND CHICKEN-POX.—The Cardiff Health Committee has decided to ask medical practitioners to notify cases of phthisis voluntarily at the same fee as for diseases notifiable under the Infectious Diseases Notification Act.—The Gloucester City Council on March 26th decided to include for one year chicken-pox in the list of diseases to be notified under the Act.

THE LABORATORY OF THE SCOTTISH ASYLUMS.—In his report on the work of this laboratory for the year 1901 Dr. W. Ford Robertson, the pathologist, states that investigations on the following subjects have been in progress during the period in question:—(1) On the Intercranial Lymphatic System, by Dr. A. C. Heath; (2) the Vascular System in Paralytic Dementia, by Dr. A. C. Ainslie and Dr. A. Aitken Ross; (3) Pathological Anatomy of Mongolian Idiocy, by Dr. David Waterston and Dr. Edwin Matthew; (4) Comparative Neuropathology (Tabes Dorsalis in Man and Nervous Disease in Horses), by Dr. D. Chalmers Watson, Dr. Isabella D. Cameron, and Dr. Isabel Watson; and (5) Pathogenesis of Paralytic Dementia, by Dr. Robertson and Dr. Lewis C. Bruce. Arrangements are being made by which bacteriological observations may be carried out upon cases of insanity by workers connected with the laboratory; Dr. Robertson considers that in this direction important results are to be hoped for. The laboratory, which is at 7, Hill-square, Edinburgh, is supported by the voluntary combination for that purpose of 18 of the Scottish asylums. The receipts for the year ended Dec. 31st, 1901, amounted to £726 and the expenditure to £721. Sir John Batty Tuke is chairman of the board of management and Dr. T. S. Clouston is the secretary and treasurer.

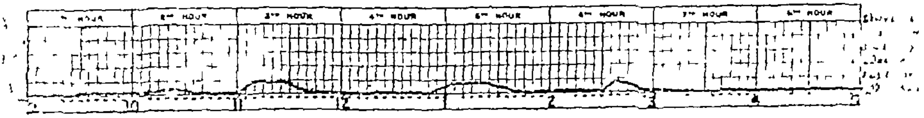
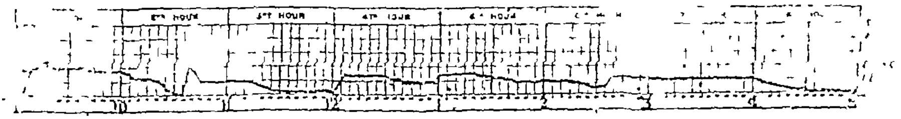
CHART 4.



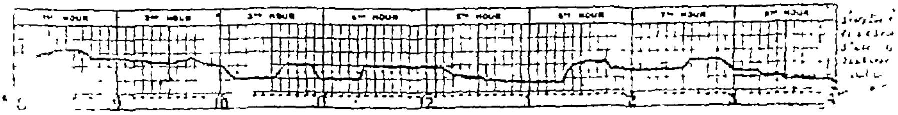
The Florence Grate; ordinary dwelling house grate; July 25th, 1901

CHART 5.



The Well Fire Grate; ordinary dwelling-house grate; August 1st 1901

CHART 6.



The Smith and Wellstood [illegible] August [illegible] coke each day, and one pound of ashes on the first day and three-quarters of a pound on each of the next two days. It was, therefore, well constructed for the proper combustion of coal, but the amount of its radiant heat[2] was small—viz., 17·88°, 15·82°, and 16·71° F., one and a half hours being occupied each day to produce it. It only required stoking four times daily.

Grate No. 4.—The Florence Grate. (*Vide* Figs. 5 and 6 and Chart 4.) This grate is made by the London Warming and Ventilating Company, Limited, and is described as fitted with improved "Jackson" back, Florence's patent automatic shaking fire-bars, and combination canopy regulator. Its size is 21 by 28 inches. The back and sides are of fire-brick. It has a fire-chamber of 18 inches and a front of vertical iron bars. In each jamb at the hearth level there is a fresh-air inlet and there is a heated air outlet over the centre of the fireplace, six feet above the floor level. The "Jackson" back and combination canopy regulator consists of a sliding door capable of easy manipulation from the front which in its two positions allows of careful regulation or adjustment of the two slotted openings, the one at the back of the fire-grate and the other at the top (*vide* section showing side elevation, Fig. 6). The smoke is drawn through the fire to a point where the heat is practically incandescent and is consumed to a very appreciable extent. The automatic shaking bars consist of a number of separate bars, preferably serrated or vandyked on their sides and upper surfaces. These are mounted loosely on a square shaft, so that the bars can rock to a limited extent on the shaft or can be rocked by operating the shaft by a handle. The bars are made abnormally deep in the body to heat the ascending air-currents As the weight of the coal varies on the different bars the bars will rock and clear the fire of ashes and dust, so allowing a continuous current of air at a high temperature to pass through the fuel which causes it to burn brightly, even in small quantities. This grate consumed for the three days respectively 20, 19, and 18 pounds of coal and left one and a half, one and a quarter, and one and a quarter pounds of coke and only three-quarters of a pound of ashes each day. The tests on the first two days lasting only for

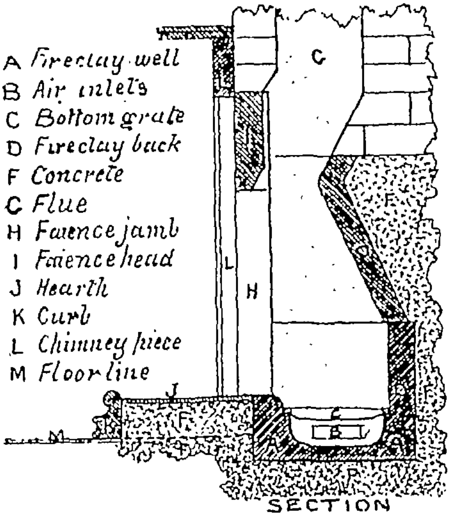
---

[2] The average radiant heat stated in the text is the daily average difference between the readings of the thermometer in the hall and those of the thermometer in front of the fire.

seven hours each, 2¼ pounds and 2¼ pounds respectively of coal must be added for those days, making the figures 22¼ pounds and 21¼ pounds. The average radiant heat was 24·80°, 25·27°, and 24·47° F. One and a half hours, one hour, and one and a half hours were required respectively to raise the temperature to this average and the grate needed stoking four times daily.

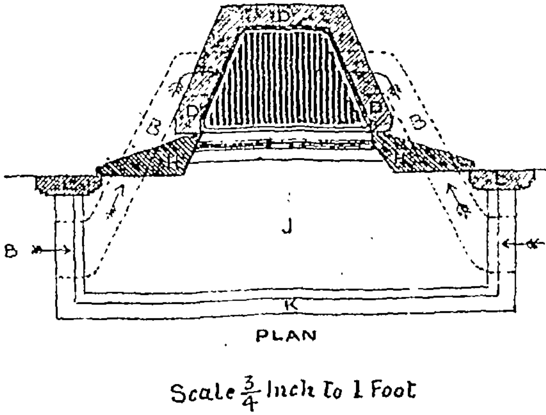
Grate No. 5.—The Well Fire (Bowes' patent) consists of a fire-basket which is composed of fireclay and a metal grating supporting the fire, under which is a fireclay well. (*Vide* Figs. 7, 8, 9, and Chart 5.) This fire burnt in the three days 28, 30, and 26 pounds of coal respectively and yielded two, two and a half, and one and a quarter pounds of coke and one and a half pounds of ashes on each of the first two days and one pound on the third day. Its average radiant heat produced each day in one hour was 20·24°, 20·65°, and 20·76° F. It was stoked five times a day.

FIG. 8.



Grate No. 5. The Well Fire. (Bowes' patent.)

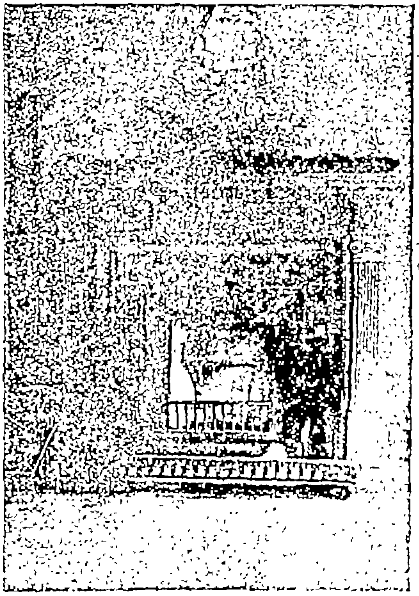
FIG. 9.



Grate No. 5. The Well Fire. (Bowes' patent.)

Grate No. 6.—This is Messrs. Smith and Wellstood's grate, of which the following is a description. The front was of cast iron and the back and sides were of firebrick. *There were ten vertical iron bars in front. The bottom of* the grate consisted of a solid iron plate portion at each end inclosing a rectangular grid of iron fire-bars with intervening air spaces. The bottom of the grate was four inches from the hearth level. The size was 38 inches by 38 inches. The fire-chamber was 18 inches in width. (*Vide* Fig. 10 and Chart 6.) This grate used in eight hours for each day respectively 27, 28, and 28 pounds of coal; it left one and a half pounds of partially consumed coal daily and one pound, one and a quarter pounds, and one and a quarter pounds of ashes, showing a good combustion. The average radiant heat was almost the same on each day, 20·37°, 20·94°, and 18·65° F. It took one and a half hours, one hour, and one hour to obtain this increase, and the grate was stoked between five and six times each day. It gave out a good heat but, as will be seen by the smoke chart, smoked badly.

FIG. 10.



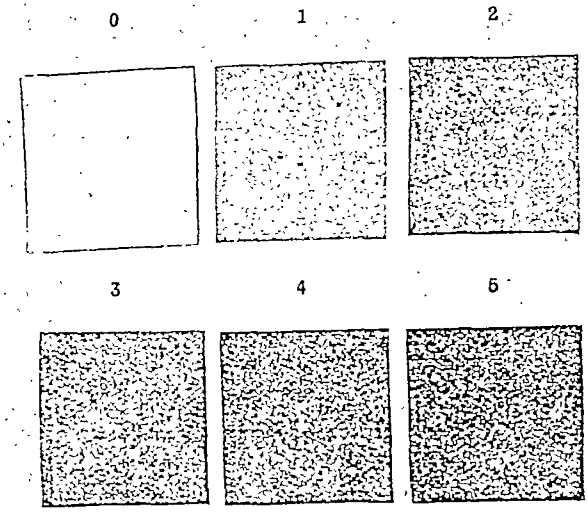
Grate No. 6 (Smith and Wellstood's).

Having now described in full the different grates and their consumption of coal and heat production a more detailed account must be given of their emission of smoke.

The following is the method adopted for calculating the comparative amount of smoke at the top of the chimney emitted by the different grates, all burning coal of the same quality and heating the same room.

If a Bryan Donkin smoke-chart be examined (*vide* Charts 1 to 6) it will be found to be divided by vertical lines into eight large sections, each of the latter being subdivided by more vertical lines into 12 smaller sections. Each of the eight sections is then divided by horizontal lines into five sections. The five sections represent the smoke-shade (*vide*

FIG. 11.



Diagrams of smoke-scale 0 to 5 (see also charts). 0, no smoke; 1, light gray; 2, darker gray; 3, very dark gray; 4, black; 5, very black.

Fig. 11), ranging from 0 (no smoke) to five (very black). The eight sections represent hours and each of the 12 subdivisions represents five minutes. From this scale or chart an average has been struck of the smoke-shade for the three days of the smoke evolved by each grate. The smoke figures thus obtained were as follows: for the ordinary grate (Grate No. 1), $\frac{8}{10}$; for the same with Lee's regulator (Grate No. 1*a*), $1\frac{1}{10}$; for the Teale (Grate No. 2), $\frac{4}{10}$; for the Tropic (Grate No. 3), $\frac{6}{10}$; for the Florence (Grate No. 4), $\frac{1}{4}$; for the Well Fire (Grate No. 5), $1\frac{1}{10}$; and for the Smith and Wellstood (Grate No. 6), $1\frac{6}{10}$.

It will thus be seen that the figures vary greatly and that whereas one grate emits an average of $1\frac{6}{10}$ for three days, out of a possible smoke shade of 5 for three days, there were degrees in gradation from this figure down to $\frac{1}{4}$ out of a possible 5, showing that, at any rate under some circumstances, the amount of smoke can be diminished largely by the use of various appliances.

Tables I., II., III., and IV. are a condensed record of the tests, tabulated so that one result can be compared with another.

The experimenters beg to express their acknowledgement of the great assistance received from Mr. R. Bailey, Controller of Stores at His Majesty's Office of Works and Public Buildings, without whose kind help the successful carrying out of these experiments would have been impossible.

The labours of the several societies and committees devoted

TABLE I.—SUMMARY OF TESTS ON SIX DOMESTIC OPEN FIRE GRATES, WITH THE QUANTITY OF COAL BURNT, THE TEMPERATURE OF THE ROOM, AND THE SMOKE OBSERVATIONS MADE, DURING THE SUMMER OF 1901, ALL USED (ONE AFTER THE OTHER) FOR HEATING THE SAME ROOM AND BURNING THE SAME SMOKY COAL. KING'S COLLEGE HOSPITAL FESTIVAL DINNER.—The annual festival dinner in aid of the funds of King's College Hospital was held at the Hôtel Métropole on April 28th, when Sir John A. Cockburn presided. In proposing the toast of the evening the Chairman said that the hospital ministered to the needs of a densely-populated area. Its income bore but a small proportion to the annual expenditure, being £2500 as against £20,000, so that £17,500 a year were needed to meet the deficiency. Additional space was necessary for several departments and for this purpose a sum of £75,000 was required. The amount of work done by the hospital was second to none of the most distinguished of the hospitals in the metropolis, and it should be remembered that it was from King's College Hospital that the results of Lord Lister's treatment which revolutionised surgery were given to the world. Subscriptions were announced during the course of the evening amounting to upwards of £1800.

THE METROPOLITAN WATER-SUPPLY.

VIII.[1]

THE KENT WATERWORKS COMPANY

AT the present time the Kent Waterworks Company supplies a larger area than any other of the metropolitan water companies. A Bill is now being promoted by the company "for the purpose of raising further monies to enable them to fulfil their statutory obligations relating to the supply of water to supply some places adjoining their district, to acquire additional lands, and for other purposes." This Bill, having been amended in some details, has passed the Parliamentary Committee and will be reported to the House of Commons for third reading[2] It is interesting to note that some of the local authorities opposed the Bill because they did not like the quality of the water The evidence on which this opinion was founded was not heard, which is, on the whole, a matter for regret In regard to the purity of the water and its freedom from organic contamination there can, as will be seen, be no doubt, and the objection taken to it was doubtless due to the fact that it is very hard—that it contains in solution a large quantity of lime salts. A conflict of expert evidence on this matter would at least have been interesting if not actually instructive Formerly part of the present statutory area of the Kent Company was actually supplied with water softened by Dr Clark's process, and there is on record some trustworthy evidence on this point which was investigated by chemists employed by the Government. To this matter reference will be made hereafter

In the year 1850 the Kent Water Company, as it was then called, obtained its supply from the river Ravensbourne at Deptford There were two reservoirs and two filter-beds at Deptford, whence the water was pumped to service reservoirs situated respectively in Greenwich Park, on Woolwich Common, and near the Marine barracks at Woolwich Between the years 1850 and 1855 one new filter-bed was made, some engine power was added, the length of the main was increased, and the supply given was either "constant" or "given daily," instead of being given only six days during each week. The same source of supply—the Ravensbourne—was at that time still used.

In the year 1852 a company was registered (Oct. 14th, under the Act 7 and 8 Vict., c. 110) to supply Plumstead and some adjoining places. The undertaking was called the Plumstead, Woolwich, and Charlton Consumers Pure Water Company The new works were "in competition with the Kent Water Company over a considerable portion of the district supplied."[3] The water supplied by the new company was obtained from a well and deep boring in the chalk which the report previously referred to states when first raised "has always an equal temperature of about 52° Fahrenheit, but the special advantage afforded to tenants of the company is that the water is softened by Dr Clark's process" When pumped the water had 21¼ degrees of hardness, 14¼ of which were derived from carbonate of lime held in solution by carbonic acid. The softening process precipitated 13 grains of carbonate of lime and left the water bright and clear and possessing only eight and a quarter degrees of hardness A description of Dr Clark's process need not here be quoted, but the advantages derived from the treatment may be briefly referred to. The Commissioners appointed to report on the matter remarked that the advantages obtained by the use of the process were three "health, comfort, and economy"

In regard to the question of health the Commissioners thought that there was no conclusive evidence as to the comparative wholesomeness of hard and soft water, and in speaking of the advantages of the softening process in regard to health they referred to the value which it was said to possess in removing in part the organic impurity which occurred in a state of solution in water To what extent this improvement occurred the Commissioners did not consider themselves able to express an opinion, but they were convinced that the process "effectually prevents the rapid vegetation which ensues on the escape of free carbonic acid from water derived from the chalk and allowed to rest." This point had, they said, been satisfactorily proved at the Woolwich works. In regard to the second point they reported that "the comfort of a soft water for personal ablution and bathing will be admitted by all as no mean consideration, in favour of the process." On the third point, that of economy, it was stated that this was effected chiefly in the saving of tea "and other articles of infusion," in soap and in soda, the saving of labour in washing and of the wear and tear of clothes, and finally in obviating the incrustation of engine boilers, kettles, and other vessels The Commissioners gave reasons for supposing that as to these points over estimates had been made, but that notwithstanding this "the great advantages of the softened water cannot be questioned and they are well worthy consideration in all places supplied with water in which the process is applicable." They further held that the softening process was advantageous chiefly to water derived from wells in the chalk and "to other waters in which the hardness is due to carbonate of lime but which have acquired no tinge of discolouring admixture."

The Plumstead Company did not prove a financial success and ultimately became bankrupt, when the plant and business were taken over by the Kent Company which then extended its area of supply to the eastward to the districts of Charlton, Woolwich, and Plumstead, in which places there was no more competition. From the middle of the last century onwards the area supplied by the company has been extending A list of the places included in the area of supply and the dates on which the extension of the business took place has already been given in THE LANCET and illustrated by a 'map showing the areas supplied by the Kent Company on different dates."

The articles on the Kent Waterworks Company[4] gave a full account of the situation of the wells, of the reservoirs, and of the means by which the water was distributed and the changes which have been made in the company's arrangements since have not been very great. There was, indeed, no necessity for great changes. The area of the Kent Company is richly supplied with water contained in the chalk. Unlike the dirty water of the Thames and of the Lea this water does not require to undergo the processes of sedimentation and of filtration All the Kent Company's water is derived from wells and all the company has done has been to sink the wells, to pump up the water, and to provide small reservoirs for its storage and pipes for its distribution. This work has been, on the whole, extremely well done Few suggestions for improvement in the works of the company could reasonably be made. The alterations which have recently been made have been designed simply to meet the requirements of a growing business. In these circumstances it is not necessary to print here a table similar to that given in the case of some of the other companies showing these recent changes. The tables previously published in this series of articles have been given to show certain flagrant delinquencies on the part of those directors of companies who have made insufficient provision for the purification of the water derived from impure sources which has been supplied to certain parts of London. In the case of the Kent Company it will be sufficient to give the general statistics published by the Water Examiner for the month of January, 1902. The amount of water pumped during the month gave a daily average of 17,284 093 gallons. No "details" are given as to how much was supplied from each of the wells belonging to the company This is a matter for regret. It is not strictly correct, moreover, for the Water Examiner to purport to give 'details of the metropolitan water-supply' and then to omit to give the amount supplied by each well in use during the month. The approximate percentage of water delivered for other than domestic purposes was 20. The number of supplies given to houses, &c., was 101,360, and of these 101 180 were given on the constant system. The estimated population supplied within the district of the company was 608,280. The total number of miles of water-pipes was 692⅜ of which 351¼ miles were within the metropolis. The number of miles of streets with water pipes constantly charged within the metropolis was

434⅓. The company possesses 16 covered storage reservoirs and these have a total capacity of 13,623,000 gallons.

The accompanying table gives the results of the analyses made by Dr. T. E. Thorpe during the year 1901 and in the month of January of the year 1902, and the table has been compiled from the monthly reports issued by the Water Examiner. It will be noticed that the result of one analysis only is given for each month and only one complete analysis apparently was made by the chemist employed by the Local Government Board. The table gives the name of the place from which each specimen was taken, the temperature of the water, and the "total hardness" of the water expressed in parts per 100,000. In regard to the hardness of the water the table is to read thus: in the January sample 100,000 pounds of water contained 28·1 pounds of carbonate of lime, or an equivalent quantity of other hardening or soap-destroying ingredients. Formerly Dr. Clark's scale was adopted universally as the standard of the hardness of water, and it is to this scale that reference was made in the analyses of the Plumstead water quoted above. In order to express the results obtained by Dr. Thorpe on Dr. Clark's scale the figures given in the table should be multiplied by seven and the decimal point moved one place to the left; thus, according to Dr. Clark's scale the sample of water taken in January had $\frac{22·7 \times 7}{10}$ degrees of hardness.

TABLE SHOWING THE RESULTS OF ANALYSES MADE BY DR. T. E. THORPE ON WATER SUPPLIED BY THE KENT COMPANY DURING EACH MONTH OF THE YEAR 1901 AND DURING THE MONTH OF JANUARY, 1902. THE RESULTS ARE EXPRESSED IN PARTS PER 100,000.

Date of collection of specimen.	Place of collection.	Temperature in degrees Centigrade.	Total solid matter.	Organic carbon.	Organic nitrogen.	Ammonia.	Nitrates as nitrates and nitrites.	Total combined nitrogen.	Chlorine.	Total hardness.

It will be noticed that the relative degree of hardness which was found in the specimens examined varied from 27·2 to 32·5. The specimens which showed the greatest degree of hardness were those taken in July and October, 1901, and in January, 1902. All these specimens, it will be further noticed, were taken from the cab-rank by Woolwich Arsenal Station. In regard to the July sample Dr. Thorpe reported that "the Kent Company's deep-well water drawn from the standpipe near Woolwich Arsenal Station was clear and of good quality, but owing to the greater proportion of salts in solution, including those causing hardness, the supply at this place was somewhat inferior to that distributed by this company in other places." In regard to the October sample Dr. Thorpe made no remark on the hardness of the water. In regard to the January specimen Dr. Thorpe observed that "as usual with samples collected near Woolwich Arsenal Station it was found to have a greater degree of hardness than the water in other districts supplied by this company." It is hardly to be supposed that Dr. Thorpe wishes it to be supposed that the *contiguity of Woolwich Arsenal* Station has any causal relation to the excessive hardness of the water drawn from pipes situated in its neighbourhood. A casual reader might, however, be led to make that inference. With the exception of the hardness of the water the customers of the Kent Company cannot reasonably make any complaint in regard to its quality. The amount of organic carbon and organic nitrogen which it contains is very small and it is clear and clean.

Should the water pumped from the district of the Kent Company be kept for the use of the people of that district it might, perhaps, reasonably be hoped that the supply would prove as sufficient in quantity as it is excellent in quality. At the present time, however, only the officials of the Kent Company know how much water is obtained from each well, and they alone know the levels at which the water now stands in each well. There is a very general idea prevailing in the rural parts of Kent that the area of the Kent Company has been unduly depleted by the abstraction of the underground water by the pumping operations of the company. Should a Water Board be established as proposed by the Government the power of abstracting water from the wells now belonging to the Kent Company would ultimately vest in a body over which the people of Kent would have practically no control. In the report of THE LANCET Special Commission on the Metropolitan Water Supply which was published in July, 1900,[5] this question was fully dealt with. It is not necessary to summarise what was there stated; it need only be said that since the date at which that report was published evidence has accumulated which has tended to strengthen and to confirm the views there expressed.

THE FOURTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

THE Executive Committee of the Fourteenth International Congress of Medicine to be held at Madrid in April, 1903, has issued the following list of theses which are to be maintained at the next meeting.

Anatomy.—1. Which is the Best Method for the Didactic Exposition of the Nervous System? 2. What is the Actual Value of Anatomical Measures for the Ethnic Determination of Individuals? *3. The Structure of the Nerve-cell. 4. The Origin of Fibroblasts in New Formations of Connective Tissue, both Normal and Pathological.

Physiology.—*1. The Physiological Action of Saccharin: should it be prescribed with food and drink or should it only be employed as a drug? 2. The Effect of Glandular Toxins upon Muscular Contraction. 3. A Bio-chemical Study of Organo-Metallic and Metallic Combinations. 4. Experimental pancreatic glycosuria.

General Pathology, &c.—*1. Parasitism in New Growths. 2. The Origin of Sarcoma. 3. Blastomycetic Lesions. *4. Suggested Revision of the Classification *and Description of Recognised Bacteria.*

Therapeutics.—1. The Relationship of the Chemical Composition of Drugs to their Physiological Action. 2. The Dangers and Emergencies of the so-called Intensive or Exaggerated Medication in Chronic

---

[5] THE LANCET, July 21st, 1900, p. 181.

Affections, especially in Tuberculosis. 3. The Utility and Dangers of Intra-vertebral Injections of Cocaine in Medicine and Surgery. 4. The *Method of the Physiological and the Remedial Action of Hypnotic and* Narcotic Drugs.

Medical Hydrology.—1. The Physico-chemical Study of the New Gaseous Elements Argon and Helium in Mineral Waters. 2. Syphilis and its Hydro-mineral Treatment. 3. Tuberculosis and its Hydro-mineral Treatment.

Pharmacy.—1. The Therapeutic Standardisation of Antitoxic Serum. 2. The Importance of the Colloidal State of the Substance in the *Preparation of Remedies and in their Pharmacological Action.* 3. Hypodermic Injections, their Pharmacological Significance and the Advantage of Issuing a Pharmacopœia which Consolidates the Methods of Preparing and Preserving these Preparations. 4. The Necessity and Utility for Remedies of a Definite Therapeutic Strength by Adopting in each case an Identical Method of Obtaining them, of Preparing them, and of Estimating their Value.

Internal Pathology.—1. The Cerebral, Cardiac, and Renal Importance of Infection. *2. The Etiology and Prophylaxis of Malaria. 3. The Pathogeny of Cardiac Arythmia. 4. The Application to Clinical Medicine of New Investigations upon the Physical and Chemical Properties of Blood-serum.

Neuropathy.—1. Toxic and Infective Manias. *2. The Etiology and Therapeutics of Psychical Conditions. 3. The Centre of Projection and Association in the Brain as Determined by Actual Pathological Anatomy. 4. The Clinical Study of Agnosia and Asymbolism. 5. The *Limitation of the Pathological Nature of Crime. 6. Of the Interven*tion of Psychiatry in the Reform of Criminals.

Pediatrics.—1. The Therapeutic Value of Serum-therapy in Diphtheria. 2. The Treatment of Clubfoot. 3. The Treatment of Tuberculous Disease of Joints. 4. The Feeding of Young Children.

Dermatology and Syphilography.—*1. Gonorrhœa from the Medico-social Point of View. 2. Parasyphilitic Affections and the Retrospective Diagnosis of Syphilis. 3. The Treatment of Pruritus. 4. The Various Forms of Purpura.

Surgery.—*1. Death after Operation. 2. The Indications for Surgical Interference in *Diseases of the Stomach.*

Urinary Diseases.—1. The Remote Effects of Surgical Interference in Cases of Malignant Tumours of the Kidney. 2. The Comparative Value of the Present Means of Learning the Functional Condition of the Kidneys.

Ophthalmology.—1. The Surgical Treatment of Affections of the *Lacrymal Tract.* 2. *The Necessity for Consolidating the Various* Optometric Scales. *3. Optic Neuritis in the Course of Acute Disease. 4. Investigations on the Action of Drugs upon the Pupil, upon Accommodation, and upon Intra-ocular Tension.

Otology.—1. The Causes of Deaf mutism. 2. The Anatomical and Clinical Study of Cholesteatomata. 3. The After-treatment of Operations on the Ear.

Rhino-laryngology.—1. Is it Advantageous from a Medical and Social Standpoint to Operate in Every Variety, in Every Phase, and at all Periods of Malignant Disease of the Larynx? 2. The Estimation of the Local Treatment of Tuberculous Disease of the Larynx. 3. Is Atrophic Rhinitis always Autochthonous? The Necessity of Establishing an Exact Diagnosis to Determine the Treatment in this Condition.

Odontology and Stomatology.—1. The Treatment and Stopping of Teeth with Diseased Pulps. 2. Dental Histology. 3. Bucco-facial and Skeletal Prothetic Appliances. 4. The Amount of Knowledge which should be Required to *Practise Dentistry* and the Methods of Teaching. 5. The Nature and Treatment of Pyorrhœa Alveolaris. 6. Local Anæsthesia in Dentistry.

Obstetrics and Gynæcology.—1. The Indications for Hysterectomy in Acute Puerperal Infection. 2. The Treatment of Placenta Prævia. 3. The Pathology and Treatment of Chronic Pelvic Cellulitis and Peritonitis. 4. The Indications and Results of Opotherapy in Gynæcology. 5. Conservative Surgery in Affections of the Uterine Annexa.

Military and Naval Medicine.—1. A Method of Solving the Problem of Tuberculosis in the Army. *2. The Advantages and Inconveniences of Compressed Drugs for Distribution to an Army in the Field. 3. The Influence of Military Life upon the Development of Affections of the Nervous System, especially on Neuroses. *4. The Hygiene of Troops at Sea and on Land on the West Coast of Africa. 5. The Prophylaxis of Syphilitic and Venereal Diseases in the Army. *6. The Cockpit in Modern Men-of-war.

Hygiene.—1. *The Necessity to Determine* the *Prophylactic Value of* Disinfection and a Criticism of the Proceedings usually Adopted. 2. The Practical Means, Individual and Collective, which are to be Adopted to Avoid the Dissemination of Dysentery. 3. The Advantage of Establishing Sanitary *Douanes* on the Land Frontiers of each Country. 4. The Advantage of Anti-tuberculous Dispensaries as a Means of Increasing the Vital Resistance of the Lower Classes. 5. Hygiene and Drains.

Forensic Medicine.—1. The Legal Significance of Wounds according to their Cause, Position, and Character. 2. The Medico-legal Idea of Deformity. 3. Discretion and Precocious Criminality. 4. The Capacity and Responsibility of Degenerates. 5. Upon the Localisation of Poisons.

Intending members of the Congress who are specially interested in the sections marked with an asterisk are requested to communicate with the Secretary-General of the Congress Dr. Fernández-Caro at Madrid.

Forms of applications for membership can be obtained from either *of the secretaries of the* National *Committee for Great* Britain and Ireland, Mr. D'Arcy Power, 10A, Chandos-street, Cavendish-square, London, W., or Dr. P. Horton-Smith, 15, Upper Brook-street, London, W. The subscription at *present* is £1.

HEALTH OF NEWQUAY.—Dr. A. Hardwick, the medical officer of health of Newquay (Cornwall), in his annual report for 1901 states that the population is estimated at 2914 and that the death-rate for the year was only 10·2 per 1000. The *report* adds that, excluding measles, which is *a notifiable disease, there were only five other cases of* infectious disease notified during the year.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE following is the report of Dr. Norman Moore, the representative of the Royal College of Physicians of London, in the General Medical Council *on the proceedings of the* Council at a special session held in February, 1902, when the differences between the Council and licensing bodies with regard to the preliminary education of the medical student were under *consideration. A full report of these proceedings* will be found in THE LANCET of March 1st, 1902, p. 626.

DR. NORMAN MOORE'S REPORT.

A special meeting of the General Council of Medical Education and Registration was held on Feb. 25th and 26th. The meeting was called to consider the report of the committee appointed on Dec. 4th, 1901, in accordance with the following resolution:—

> That a committee be appointed to prepare a report on the differences that exist between certain licensing bodies on the one hand, and the General Medical Council on the other, regarding the courses and conditions of study and the recognition of the institutions and schools in which the required courses may be taken, and that the report be considered by the Medical Council at a special meeting, when the Council will decide what action, *if any, shall be taken, and in particular* whether the circumstances are such as to require action to be taken under Section XX *of the Act of* 1858.

The report of the committee is printed at length in the minutes of the Council (vol. xxxix., p. 70). It showed that the regulations of the University of Oxford, of the University of London, and those of the Royal College of Physicians of London and the Royal College of Surgeons of England differ in several particulars from the recommendations (sometimes called by the Council "requirements") of the General Council of Medical Education and Registration. The four bodies named agree in not requiring registration in the General Council's Register of Medical Students. The University of Oxford and the University of London in their regulations perhaps differ on the greatest number of points from the Council. The Royal College of Physicians of London and the Royal College of Surgeons of England differ in fact at present: (1) in not requiring the registration of a student in the Register of the General Council, and (2) in relation to the places at which courses of study in chemistry, physics, and biology may be taken after passing a preliminary examination in arts.

The committee issued eight recommendations. The first five of these stated that in consequence of these differences of regulation or acceptance of students who have worked under varying regulations the qualifications of—

The Royal College of Physicians of London,
The Royal College of Surgeons of England,
The University of Oxford,
The University of London,
The Royal College of Physicians of Edinburgh,
The Royal *College of Surgeons of Edinburgh,*
The Faculty of Physicians and Surgeons of Glasgow,
The *Society of Apothecaries of London,*

do not secure that the persons holding them possess the requisite knowledge and skill for the efficient practice of their profession.

Clause VI. *recommended* that the Council should, after preliminary warning, represent this fact to the Privy Council in November, with a view to deprive the above bodies of their power of granting qualifications to practise unless they altered their regulations.

A minority consisting of the Representative of the Royal College of Surgeons and myself presented a minority report, as follows:—

> I. Having considered the numerous differences in detail as to the courses of professional study required by the several qualifying bodies, we are of opinion that, even if it were desirable, it is impossible to obtain absolute uniformity and recommend the Council to withdraw its late resolution requiring the approval by the General Medical Council of the scientific institutions recognised as places of study by the qualifying bodies.
> II. We are of opinion that the powers claimed by the Council in this particular do not exist.

The prefatory narrative of the report, with the appended observations and conclusions, were proposed for adoption and the proposal was carried.

The tone of the discussion was *adverse to the adoption* of the recommendations of the report, and Dr. McVail, chairman of the committee, asked leave of the Council to withdraw the recommendations, and the leave was granted without a division. On the motion of Dr. Macalister, seconded by Dr. McVail, the Council then resolved:—

I. That the Council, under the powers granted by Section XVIII. of the Medical Act, 1858, require the Examining Board in England to furnish the Council with the following information regarding the courses of study in chemistry, physics, and biology to be gone through by candidates for the qualifications L.R.C.P. London and M.R.C.S. England, namely—

In respect of each of the teaching institutions recognised by the Royal Colleges but not approved by the Council,

(*a*) What are the methods of instruction, theoretical and practical, adopted in the subjects of chemistry, physics, and biology?

(*b*) What time is devoted by students to the recognised courses of study in each of these subjects?

(*c*) What subjects, other than chemistry, physics, and biology, are students permitted to study simultaneously with these subjects?

(*d*) What were the ages at the commencement of the recognised courses in these subjects of the students on whose behalf certificates of study were accepted by the Examining Board in the year 1901?

(*e*) What are the names and qualifications of the teachers of chemistry, physics, and biology, who give the recognised courses in these subjects?

II. That it is desirable that, under the powers given by Section XVIII. of the Medical Act, 1858, the examinations in chemistry, physics, and biology held by the several licensing bodies should from time to time be visited and reported on.

III. That in the first instance the examinations in chemistry, physics, and biology held by the Examining Board of the Royal Colleges in England during the present year be visited by two persons appointed by the President on behalf of the Council and that they be instructed to report on the scope, standard, and sufficiency of these examinations.

As the Council has no power of visitation of institutions, and no power to compel this College to visit the institutions it recognises for any part of the course, and as some of this information could only have been obtained in the process of visitation, it seems doubtful whether the Council can properly require all this information under Section XVIII. of the Medical Act of 1858, and it might be wise to ascertain the precise duties of the College under the Act in this particular; but as the Council may justly wish to be informed on everything relating to medical education, I think it would be right to furnish this information, so far as our records enable the College to do so, on the present occasion, and I spoke to this effect in the Council.

The early examinations of the qualifying bodies have not hitherto been visited, and whether the Council has power to visit them under the Medical Acts may, perhaps, be uncertain. Even if the power be non-existent in the Council our College would probably raise no objection to the proposed visitation; but it is clear that the visitation of the corresponding examinations of all the qualifying bodies should take place before this part of medical education can be fully discussed by the Council.

Throughout the prolonged discussion at the Council on the regulations of our College as regards the first year of medical study, now I hope concluded, I have endeavoured to make clear to the Council that as the powers of the College as regards its own curriculum rest not only upon Acts of Parliament and charters, but also upon its obvious competence to deal with questions of medical education, it cannot permit any encroachment upon its sphere of responsibility, but that it will always in the future, as it has since the General Council came into existence, do all in its power to aid the Council in the duties which the Medical Acts have prescribed for it.

(Signed) NORMAN MOORE
(Representative of the College in the Medical Council).

April 23rd, 1902.

Looking Back.

FROM

THE LANCET, *SATURDAY, MAY* 8, 1824.

ST. BARTHOLOMEW'S HOSPITAL.

The accidents admitted here this week are a fractured patella, dislocation of the left os humeri; fracture of the tibia and fibula; case of cut throat, and a child with a severe burn.

Sir LUDFORD HARVEY has resigned his situation as surgeon to this institution; Mr. LAWRENCE will succeed him. There are three or four candidates for the assistant surgeonship, but we are unwilling to say any thing at present about the election, that may injure either party. But there is one circumstance to which we must allude, which is, that one of the candidates has not served an apprenticeship to the hospital, and if he be duly qualified for the post, (which we believe him to be) we should be heartily glad for him to obtain it. The present system of electing hospital apprentices to fill the office of surgeons in preference to all others, without any reference to the respective merits of the candidates will not, we feel convinced, last very long. The medical profession in this country has existed for centuries without being subjected to the controul of the press; but the times are changed, and we trust that the repeated exposure of existing abuses will at last produce their reformation.

WESTMINSTER HOSPITAL.

JOHN LONGHURST, who was admitted into this hospital under the care of Sir ANTHONY CARLISLE, a month ago, with a fractured patella, is recovering very rapidly; the bone is united closely, so much so, that instead of the depression felt usually in these cases on its surface, a small narrow edge[1] is plainly perceived, thus clearly proving that the two portions of bone are adhering to each other, by an osseous deposit having taken place, and that the mode of treating such cases, by bringing the fractured parts together, is superior to any in use at the present day.

NOTICE TO CORRESPONDENTS.

We will comply with Y.'s request, and give a case in Latin next week.

The Index to Vol. I. was published with the first number of Vol. II. It is again out of print, but will be reprinted in a few days.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8713 births and 4724 deaths were registered during the week ending May 3rd. The annual rate of mortality in these towns, which had been 18·3 and 17·0 per 1000 in the two preceding weeks, further declined to 16·6 last week. In London the death-rate was 15·7 per 1000, while it averaged 17·0 in the 75 other large towns. The lowest death-rates were 7·6 in Hornsey, 8·5 in Reading, 8·6 in King's Norton, 9·4 in Devonport, 10·3 in Walthamstow and in Derby, and 11·1 in Leyton and in Wallasey; the highest rates were 22·2 in Stockton-on-Tees, 22·5 in Hanley, 22·8 in Blackburn, 23 0 in Tynemouth, 23·7 in Wigan, 24·5 in Oldham, 24·8 in Rochdale, and 25·5 in St. Helen's. The 4724 deaths in these towns last week included 489 which were referred to the principal zymotic diseases, against 596, 550, and 534 in the three preceding weeks; of these 489 deaths 138 resulted from whooping-cough, 98 from measles, 64 from small-pox, 63 from diphtheria, 48 from scarlet fever, 39 from diarrhœa, and 39 from "fever" (principally enteric). In Hornsey, Norwich, Plymouth, Coventry, Swansea, and seven other smaller towns, no death from any of the principal zymotic diseases was registered; while the highest zymotic death-rates were recorded in West Ham, Grimsby, Bolton, Burnley, Barrow, South Shields, and Rhondda. The greatest mortality from measles occurred in Northampton, Burton-on-Trent, Barrow-in-Furness, Rhondda, and Merthyr Tydfil; from scarlet fever in Wigan and in Bolton; from whooping-cough in West Bromwich, Aston Manor, Grimsby, Bolton, South Shields, Gateshead, and Newcastle-on-Tyne; and from "fever" in Aston Manor. The mortality from diphtheria showed no marked excess in any of the large towns. Of the 64 fatal cases of small-pox belonging to these towns registered last week 43 belonged to London, 13 to West Ham, two to Tottenham, two to South Shields, one to Willesden, one to East Ham, one to Oldham, and one to Rhondda. The number of small-pox patients in the Metropolitan Asylums hospitals at the end of last week was 1442, against 1431 and 1515 at the end of the two preceding weeks; 250 new cases were admitted during the week, against 274, 328, and 367 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 2146, 2155, and 2188 on the three preceding Saturdays, had further risen to 2222 on Saturday last; 258 new cases were admitted during the week, against 264, 269, and 283 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 299, 316, and 315 in the three preceding weeks, further

THE LANCET.

LONDON: SATURDAY, APRIL 5, 1902.

The New Royal Warrant for the Army Medical Service.

IN calling the attention of our readers to the Royal Warrant for the Army Medical Service, the text of which appeared in THE LANCET of March 29th, p. 912, we deemed it necessary to point out that it should not be regarded as embodying in full the intentions of the Government in respect of army medical reform and reorganisation. Although the new Warrant is a lengthy and somewhat complicated document which requires to be carefully read and to be considered in detail there are several important points which, being foreign to a Royal Warrant, do not find any place in it and concerning these and others which suggest themselves we have still to await further information. For instance, we have yet to learn a good deal about such matters as the following: the number and nature of the new examinations; the functions of the Advisory Board and the limits circumscribing its sphere of action; the provisions to be made for study-leave for medical officers and for the establishment of the proposed army hospital and medical school in London; the organisation of an army sanitary department during times of peace and of war; and the attachment of medical officers to regiments and the way in which this is proposed to be carried out. These are all matters of public and not merely of departmental interest, because they have a direct bearing on the future efficiency of the Army Medical Service. There is, moreover, the question of the pay and position of medical officers in India and it is imperative that this should receive a satisfactory answer.

With respect to the examinations we are assured that the competitive examination on entrance will be made as practical and clinical in character as possible and that the others will be of such a nature as is really needed for the protection of the service and in the interests of the medical officers themselves. We do not profess to attach the value to examinations as a test of what is wanted in a medical officer that many do. The medical candidate for the army has, as a rule, only just been emancipated from a series of examinations in order to obtain his professional qualifications and there is consequently the less need to subject him afresh to such tests at an early stage of his career.

The present position and pay of officers of the Royal Army Medical Corps, whilst serving in India, is a matter of such importance that we cannot believe that the War Office authorities will be content to leave things as they are and thereby imperil the success of their scheme—as they assuredly will if nothing be done. As we understand the position, the War Office of this country regards any independent authoritative action on its part in this respect as *ultra vires;* and that the consent of the Indian Government to any scheme affecting medical officers in the pay of, or serving under, that Government should first be obtained, is, officially speaking, obviously reasonable and right. But Mr. BRODRICK, when introducing the army estimates for the coming year and putting forward his much larger scheme of army reform, had to encounter and to overcome not only the opposition of the Chancellor of the Exchequer in this country but also that of the Secretary of State for India on the ground of the great additional expenditure involved by it. So must it be in the present case. It is, moreover, pertinent to remark that there is every reason why the Indian Government should deal justly and even generously with the medical officers serving with British troops in India, seeing that when the station-hospital system was introduced many years ago into that country it gave rise to a very large saving to the Indian Government, not one penny of which was appropriated to the benefit of the medical officers; indeed, the introduction of that system, while adding greatly to their responsibilities and labours, actually deprived them of some pecuniary advantages.

We may say, in conclusion, that we see no reason for altering our first impressions of the new Warrant—namely, that it contains many new and excellent points and that taken as a whole it is a good Warrant; and having no sort of doubt that Mr. BRODRICK was, and is, sincerely desirous of making it satisfactory to the country and to the profession, we confidently look to him to see that it is interpreted and carried out in a wise, just, and liberal spirit.

The Housing of the Poor.

WE recently published[1] an appeal for funds on behalf of the Mansion House Council on the Dwellings of the Poor addressed to us by Sir JOSEPH DIMSDALE who has been its honorary treasurer for several years and who during the present year is also its chairman by virtue of his office of Lord Mayor of London. The Mansion House Council is an admirable association carrying on an excellent work effectively but quietly, so that many who might be willing to support it are possibly quite unaware of its existence and its aims. Founded in 1883 it has for its object the improvement of the homes of the poor in the metropolitan district and it seeks to effect that object by enforcing the Sanitary Acts and by spreading, as far as it is able, the knowledge of sanitation among the people. In cases where the enforcement of the Sanitary Acts is clearly the duty of a local authority, but where that authority is uninformed or is wilfully neglecting its duty, the Mansion House Council presses the matter upon the attention of the lagging public body, so that the necessary stimulus is imparted and the steps prescribed by law are taken.

The Mansion House Council employs but three paid inspectors, who make about 8000 inspections in the course of a year, and the bulk of its operations all over the metropolis is carried on by local committees and voluntary helpers. A society, however, that organises and directs, even though it may employ voluntary assistants, cannot live without funds declined last week to 240 and were 54 below the average. The causes of 68, or 1·5 per cent., of the deaths in the 76 large towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Newcastle, and in 47 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Aston Manor, Leicester, Liverpool, Middlesbrough, and Stockton-on-Tees.

[1] THE LANCET, March 15th, 1902, p. 772.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24·6 and 21·1 per 1000 in the two preceding weeks, further declined last week to 18·9 per 1000, but was 2·3 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 15·8 in Edinburgh and in Aberdeen to 21·1 in Paisley and 23·4 in Greenock. The 612 deaths in these towns included 28 which were referred to whooping-cough, 23 to diarrhœa, 15 to measles, five to "fever," four to diphtheria, two to scarlet fever, and one to small-pox. In all 78 deaths resulted from these principal zymotic diseases last week, against 63 and 70 in the two preceding weeks. These 78 deaths were equal to an annual rate of 2·4 per 1000, which was 0·7 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 21 and 29 in the two preceding weeks, fell last week to 28, of which 16 occurred in Glasgow and six in Aberdeen. The deaths from diarrhœa, which had been 10 and 17 in the two preceding weeks, further rose last week to 23, and included 14 in Glasgow and three in Dundee. The fatal cases of measles, which had been 10, 18, and 13 in the three preceding weeks, rose again last week to 15, of which five occurred in Edinburgh, five in Dundee, and four in Glasgow. The deaths from scarlet fever, which had been eight, two, and five in the three preceding weeks, declined again last week to two, one of which occurred in Edinburgh and one in Greenock. The fatal cases of diphtheria, which had been seven and four in the two preceding weeks, was again four last week, of which two occurred in Glasgow. The deaths from fever, which had been five, four, and one in the three preceding weeks, rose last week to five, of which three occurred in Glasgow and two in Greenock. The fatal case of small-pox was registered in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 188, 199, and 161 in the three preceding weeks, further fell last week to 138 and were slightly above the average in the corresponding period of last year. The causes of 25, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·0 and 26·8 per 1000 in the two preceding weeks, declined again last week to 24·9 per 1000 during the week ending May 3rd. During the past four weeks the death-rate has averaged 25·4 per 1000, the rates during the same period being 17·1 in London and 19·3 in Edinburgh. The 181 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 14 from the number in the preceding week, and included nine which were referred to the principal zymotic diseases, against 10 in each of the two preceding weeks; of these, three resulted from measles, three from "fever," one from diphtheria, one from whooping-cough, and one from diarrhœa. These nine deaths were equal to an annual rate of 1·2 per 1000, the zymotic death-rate during the same period being 2·0 in London and 0·3 in Edinburgh. The fatal cases of measles, which had been two in each of the two preceding weeks, increased last week to three, while the three deaths from "fever" showed a slight decline from the number in the preceding week. The 181 deaths in Dublin last week included 21 of children under one year of age and 52 of persons aged upwards of 60 years; the deaths of infants being considerably below, and those of elderly persons rather above, the numbers in recent weeks. Seven inquest cases and three deaths from violence were registered; and 70, or more than a third, of the deaths occurred in public institutions. The causes of eight, or more than 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

Royal Navy Medical Service.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet Surgeon I. H. Anderson has been placed on the retired list at his own request, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets. Dated April 30th, 1902.

Staff Surgeon W. J. Maillard, V.C., has been placed on the retired list of his rank. Dated April 7th, 1902.

The following appointments are notified:—Staff Surgeon G. T. Collingwood to the *Sutlej*. Surgeons: E. T. P. Eames to the *Jupiter* and M. J. O'Regan to the *Sans Pareil*.

Army Medical Service.

Surgeon-General O. MacDonagh Cuffe, C.B., is placed on retired pay.

Major T. C. McCulloch, R.A.M.C., to be a Deputy Assistant Director-General, vice Major W. G. Macpherson, R.A.M.C., whose period of service in that appointment has expired. Dated May 1st, 1902.

Royal Army Medical Corps.

Lieutenant-Colonel Richard Henry Quill to be Colonel, vice R. C. Eaton, deceased. Dated March 16th, 1902.

Lieutenant-Colonel R. Drury retires on retired pay on account of ill-health.

Captain Frederick Smith, D.S.O., to be Major. Dated March 30th, 1902.

Lieutenant-Colonel W. B. Slaughter is ordered to Salisbury Plain for duty at the temporary General Hospital, Bulford Camp. Lieutenant T. Finucane has been transferred to the Punjab Command from Bombay.

Imperial Yeomanry.

Suffolk (The Duke of York's Own Loyal Suffolk Hussars): Surgeon-Lieutenant Sir F. Treves, K.C.V.O., C.B., resigns his commission.

Volunteer Corps.

Royal Garrison Artillery (Volunteers).—1st Argyll and Bute: Surgeon-Lieutenant T. H. Thomson to be Surgeon-Captain. 2nd Devonshire: The resignation of Surgeon-Lieutenant H. W. Webber, which was announced in the *London Gazette* of April 22nd, 1902, is cancelled.

Rifle: 5th (Glasgow Highland) Volunteer Battalion, the Highland Light Infantry: William Ritchie to be Surgeon-Lieutenant.

South African War Notes.

Lieutenant Beatty, R.A.M.C., reported dangerously ill showed a slight improvement on May 5th.

Major J. P. S. Hayes, R.A.M.C., Lieutenant P. H. Falkner, R.A.M.C., and Civil Surgeon McCrea are returning from South Africa to England.

Memorial to Members of the St. John Ambulance Brigade.

On June 11th, at 12.30 P.M., the Prince of Wales, Grand Prior of the Order of the Hospital of St. John of Jerusalem in England, will unveil the memorial to the members of the St. John Ambulance Brigade who have died while on active service in South Africa. This memorial has been erected by the King and the Chapter-General of the Order in St. John's Church, Clerkenwell.

Colonial Troops' Entertainment Committee.

Earl Roberts and the Earl of Jersey have joined the Colonial Troops' Entertainment Committee. The colonel and officers of the 20th Middlesex (Artists) Corps have forwarded to the committee an invitation to a regimental smoking concert for the officers and non-commissioned officers of the various contingents who are coming to England for the Coronation.

VACCINATION EXPENDITURE.—At the meeting of the St. Columb Board of Guardians held on April 18th it was reported that the vaccination fees for the past quarter amounted to £53, being double the amount for the corresponding quarter of 1901. It was stated that one public vaccinator vaccinated his own child and charged 8*s.* for the operation and another vaccinated himself and his wife and charged 2*s.* 6*d.* in each case. In reply to a question the clerk remarked that the Local Government Board stated that persons who were vaccinated by the public vaccinator were not to be considered as paupers, but the chairman said that he was of a contrary opinion.

Correspondence.

"Audi alteram partem."

PAYING WARDS AND PAYING HOSPITALS.

To the Editors of The Lancet.

Sirs,—I am rather sorry to see that no notice has been taken of Sir Henry Burdett's letter, as the subject is one of great importance to the medical profession and its bearings deserve careful consideration. In America there is a good deal of complaint on the part of the profession of paying hospitals with salaried staffs which have been started as commercial undertakings and pay a dividend to their shareholders. A medical paper, writing of one of these institutions, tells us that it offers physicians, nursing, board, washing, and everything necessary for 12 dollars a week during sickness and an annual subscription of 12 dollars a year. That is to say, for an annual subscription of £2 8*s.* any person can insure all needful hospital accommodation with medical or surgical assistance in case of illness at the very moderate cost of £2 8*s.* a week. It is complained of these institutions that they cater for classes which are financially well off and that they are enabled to make a profit at the expense of the medical profession

Everyone recognises the advantages of hospital organisation and hospital methods in the treatment of disease and sympathises with the desire to bring these advantages within the reach of the class that lies between the rich, for whom there are nursing homes, and the poor, who have the charitable hospitals. There is probably no special difficulty in organising such institutions and they could be more economically administered if connected with charitable hospitals, as Sir Henry Burdett recommends, as they would thus escape many heavy establishment charges. It might be possible to provide bed, food, washing, nursing, and medicines for 25*s.* or 30*s.* a week, and if the case needed only the attendance of a general practitioner the expenses of the illness would probably be less than at home. But surely the success of hospital treatment is not solely dependent upon good sanitary surroundings and disciplined nursing. The special skill of the visiting staff counts for something, and I should like to know how their services are to be obtained for persons paying £1 10*s.* or £2 a week? I do not go so far as to say that we should always charge full fees or nothing, but it must be admitted that there is a difficulty about reducing fees unless the considerations for which the reduction is made can be quite well defined. Speaking for myself, I should have no objection to seeing cases in such a paying hospital at half my usual fees if there were some means of ascertaining that the patient was unable to pay more; but how is this to be done without an inquiry such as is generally resented? If paying wards are to form a dependence of a charitable hospital it should be understood (1) that the members of the visiting staff of the hospital are not obliged to undertake the charge of patients in the paying wards as part of their duty to the hospital; and (2) that for their attendance upon patients in the paying wards they should be paid by fees fixed according to a reduced scale to be hereafter agreed upon.

The fixing of this schedule of reduced fees would have to be done by a conference between the administration and the medical staff. Supposing this difficulty got over the staff would naturally desire to prevent well-to-do persons taking advantage of these reduced prices. I can only see two ways in which this can be done, either by confining admission to people with incomes below a certain limit or by leaving the work to be done by the junior members of the staff. I do not think the second plan would be altogether satisfactory and there are obvious but not insuperable objections to the first. In considering all these questions we must bear in mind that we have to satisfy the just claims of the medical profession on the one hand and the requirements of the public on the other. It seems extremely probable that such hospitals will be established and it will be better for the medical profession to consider the conditions under which such institutions can be made, if not free from all objection, as free from objection as possible.

I am, Sirs, yours faithfully,

Birmingham, May 6th, 1902. Robert Saundby, M.D. Edin.

THE BATTLE OF THE CLUBS.

To the Editors of The Lancet.

Sirs,—In view of the correspondence which you have recently published on the question of club practice and contract work I think it may not be inopportune to narrate as shortly as possible what has been achieved by the medical practitioners of Stockport during the past seven years and to draw certain deductions from their many experiences. In 1895 there were some 40 clubs in the town, under the care of various medical men; the rate of pay was 2*s.* 6*d.* per head per annum. These clubs were approached with a view to raising the rate to 4*s.* 4*d.* per annum, together with various other conditions, including an examination fee on entrance and a wage limit. *Two* clubs *only* accepted the proposed scheme and with these matters have run smoothly ever since. The reception vouchsafed to the proposed reforms by the 38 remaining clubs was varied; the contumely and contempt expressed towards the "medical profession" were unanimous. Failing reform, in 1896 the "profession" resigned in an equally unanimous manner, as *two* medical men only declined to join their brethren. Since that time the clubs here have been without doctors, with the above-mentioned exceptions, and in those cases the payment has been raised to 4*s.* 4*d.* The experience of years has proved to the clubs that they can do very well without medical men, and the latter have come to the conclusion that the former are a good riddance. And thus peace is reigning. A so-called provident dispensary has existed in the town for some 10 years. The local medical society, seeing and seizing an opportunity, took over the medical management of this institution last August, the object being "to end it or mend it." I inclose a report, drawn up and presented to the managing committee, which will explain the working of the concern and the conclusions arrived at by the medical men after a four months' experience of the work. The Stockport Provident Dispensary was disbanded by resolution of the committee and members at the end of 1901.

Now I have taken a great interest and an active part in this matter from the beginning, and with the knowledge and experience gained in the past seven years I hope I am now able to make some useful deductions for the benefit, firstly, of the profession to which I belong, and secondly, for the friendly societies and all who desire to encourage thrift and providence, but not at the expense of any one section of the community. The whole matter is one of business pure and simple and philanthropy and charity do not enter into the question at all. The friendly societies have declared openly that they ask no concessions and disclaim any suspicion of charity in their dealings with medical men. From what I know of these societies I thoroughly believe their sincerity; their business instincts are good, their financial position is secure, and they are subject to adequate supervision and control. The medical profession has hitherto failed to meet them in a businesslike manner. Medical men are lamentably lacking in business methods. How many know what they can legally deduct as "practice expenses" in making an income-tax return? How many have the very faintest idea what it costs to see a patient? Can one in a hundred state the *average* cost of an eight-ounce bottle of medicine? I cannot understand how any solution of the present difficulty with respect to club and contract work can ever be found unless some data can be established on which to base charges for visits and consultations. I have done my little towards elucidating the matter and made calculations some years back which may be of value. I have not kept the exact figures but the result was so uniform over a period of four years that the details are immaterial. From 1893 to the end of 1896 my practice was a general working-class. I kept a horse and trap and a dispenser. The radius of my work rarely extended more than one and a half miles from my house. The district was thickly populated and found employment for about one medical practitioner to every 1600 inhabitants. I had between 500 and 600 club patients, all at 2*s.* 6*d.* per head per annum. An analysis of two years' work for them, 1893 and 1894, showed that I *received* 5¼*d.* for each consultation at my surgery, or each visit at their homes, medicine included. A calculation made on the *whole work* of the practice showed that the actual *cost* to me of each consultation or visit, including medicines, averaged for the four years 1*s.* 2*d.* each. It is thus evident that the club portion of the work acted as a serious discount on the remainder. Since giving up club practice the expense per visit has fallen somewhat and now probably averages 1*s*. I do not consider 1*s* or 1*s* 6*d* an "exorbitant" charge, in addition to out-of-pocket expenses, for my time, skill, and trouble in the case of each patient seen. It may be of interest to note that my drug and bottle bill amounted to about one-sixth of the total practice expenses. I have entered thus minutely into details in the hope of eliciting similar expression of experiences from my professional brethren. I do not see how we can come *to any agreement with the friendly societies without some* such basis as a standpoint for our demand for a higher rate of remuneration. If we can fairly prove that the actual cost of seeing a patient is 1*s* and that we expect a minimum of 1*s* as a fee for our skill and time, the societies can have very little further argument to bring, as they say here, "they may take it or leave it." To obtain this rate of remuneration the annual club contribution would have to be raised to quite 10*s* per head on my experiences. But, after all, what necessity is there for "contract work" at all? It is debasing sort of work, hardly better than gambling; the patient wants *his money's worth and will see that he gets it*, *the medical* man is harassed and worried at all times with trivialities and is generally regarded with suspicion, and has for ever lost that possession "independence" so dear to the "working-man," though perhaps equally dear and less often acquired by the harder "working doctor." Now my solution of the question is simple enough; it can be attained in a little time with a little trouble. It cannot be settled either by the General Medical Council or by conciliation boards, nor can the assembled friendly societies "bring the doctors to their knees." It is a matter *for local arrangement and district medical societies in* collaboration with the friendly societies have the solution in their own hands. The means are as follows in any given district.

1. As many medical men as possible must undertake to ascertain by a uniform system of account and bookkeeping the actual average cost of seeing patients for one year. This amount plus 1*s* to form the *minimum* charge for a surgery consultation or a day visit within a given distance. The accuracy of this estimate may be checked by continuing the investigation for three years and then correcting the *result on the longer experience*.

2. The medical men draw up a "tariff" based as above, with extra charges for night visits, or visits outside a certain radius; also a charge for "repeat medicines" where no visit is made or consultation given. This should be as small as possible in order to discourage the detestable tendency to making the charges depend on the quantity of physic that can be got down people's throats. Other services, operations, &c., can be readily priced in such a tariff.

3. The clubs are provided with the names of medical men willing to attend members on tariff charges. The clubs will be responsible for the payment of accounts up to the amount as specified in the tariff. The members select their medical attendant from the list, and in their relationship with him they are exactly as any ordinary private patient; they are mutually dependent and independent, and changes can be made in accordance with the wishes and proper custom of either party. This arrangement quite overcomes the "wage limit" difficulty. Any medical man can decline any patient he thinks fit on any ground or can accept him on the condition that the charges will be in excess of the tariff, the patient being responsible for the excess. If any medical man accept a well-to-do patient on tariff charges it is his own look-out.

4. The tariff charges will be slightly lower than the usual charges for persons in similar position on account of the security for payment afforded by the society.

5. Women and children can be admitted at similar rates to adult males and under similar circumstances. The sole objection I can see to my suggestion is that it will entail the friendly societies paying 10*s* per head per annum unless I have very much over-estimated the cost of working-class practice. I do not think I have been lavish in my treatment, but I know I never heard of any complaint from my club patients, so I trust my estimate is as it should be. If my estimate is more than can be raised as a levy the societies must pay what they can in the form of a dividend towards their members' doctor's bills, leaving the balance to the individual liability. After all said and done there is no inherent antagonism between the medical profession and the friendly societies. It is a matter for "collective bargaining" on businesslike lines, but unfortunately the collectivism has hitherto been all on the side of the societies and the ununited medical profession has been individually a sufferer in consequence.

I am, Sirs, yours faithfully,
BASIL W. HOUSMAN, F.R.C.S. Eng.

Stockport, April 28th, 1902.

THE NEW SYDENHAM SOCIETY'S CLINICAL ATLAS OF MEDICINE AND SURGERY.

To the Editors of THE LANCET.

SIRS,—Arrangements are being made to publish as early as practicable a fasciculus illustrating the effects of arsenic in producing affections of the skin, &c. The subject is one of great interest at present and likely to become of yet more.

Will you permit me through your pages to ask those of your readers who may chance to possess original drawings illustrating these conditions to do our council the favour of allowing us to inspect them? They may be sent either to the Museum at the Polyclinic, 22, Chenies-street, or to myself, and will be taken good care of.

I am, Sirs, yours faithfully,
JONATHAN HUTCHINSON,
Honorary Secretary of the New Sydenham Society.

15, Cavendish-square, W., May 7th, 1902.

CARDIAC INADEQUACY.

To the Editors of THE LANCET.

SIRS,—It certainly seems paradoxical to suggest that a man may die from cardiac failure without cardiac dilatation—with contracted hypertrophy and not dilated hypertrophy, but the facts of the case in the first of the two instances which I adduced do not seem to bear any other interpretation. The patient had, at least after death, a small heart with hypertrophied walls and relatively small cavities. His liver was enlarged and *without* interstitial cirrhotic change. His kidneys were large and certainly had, according to the pathologist's report, adherent capsules but were not examined microscopically and during life the patient's urine was of high specific gravity and showed no albumin. Sphygmograms taken periodically and carefully by a most efficient resident physician—Dr. A. Whitmore—showed a progressive fall in the force of ventricular systole after a temporary rally when the patient was first admitted to hospital and relieved of the burden of ascites. To the second case which I recorded, as Dr. H. Campbell perceives, I do not attach the same value, although I consider that the small heart even here added to the general embarrassment of the patient. It is the paradoxical element in the situation which adds to its interest. If Dr. Campbell can suggest any more satisfactory solution to the conditions involved and convict me of error I shall be the first to acknowledge myself in fault, but I confess I cannot see my way to doing so at present.

I am, Sirs, yours faithfully,
ALEXANDER MORISON.

May 4th, 1902.

LARGE DOSES OF STRYCHNINE IN SURGICAL SHOCK.

To the Editors of THE LANCET.

SIRS,—Dr. Gordon Sharp has failed, in his letter in THE LANCET of April 26th, p. 1210, to distinguish between the effects of 50 minims of liquor strychninæ introduced in one dose into the circulation of a non-collapsed patient and the effects of the same amount divided into smaller doses and administered at intervals of 15 minutes to a patient in a state of collapse. In practice this difference is very marked. In the case referred to by Dr. Sharp the total amount administered was 50 minims of the liquor given in the space of one and a half hours, not 70 minims in three hours.

Dr. Sharp asks: "Do the surgeons never find disagreeable tonic and clonic spasms of the muscles of the extremities remaining after the effect of the anæsthetic has passed off?" These inconveniences have, in my experience, been conspicuous by their absence, but in the event of their appearing they would be very preferable to death of the patient from heart failure. The theory of the terrific spasms which ought to occur is perfect but it would have more weight if backed by details of a few cases in which these fearful after results have actually appeared. Doubtless Dr. Sharp can supply such. Symptoms of poisoning following a single large dose of strychnine in a healthy patient are well known but have no bearing on the point at issue. The following case which has occurred since my last letter is a further instance of the value of strychnine in large doses in threatened death from heart failure.

A man, aged 49 years, with obstruction of five days' standing and stercoraceous vomiting, had cœliotomy performed. For the first half hour local anæsthesia by eucaine was employed, but a more extensive operation becoming necessary I administered ether and oxygen from a Rumbold-Burch inhaler during the last hour only in sufficient quantities to keep the patient partially anæsthetised. During the first half hour the pulse was small; the rate was 110. Coincidently with the administration of the general anæsthetic the pulse became very small and rapid; the rate was about 160 during the last hour. I injected into the pectoral muscles at intervals of about 10 minutes the following doses of liquor strychninæ (made up to 1 in 100), two doses of 10 minims and three doses of 15 minims, the patient getting 65 minims of liquor strychninæ (1 in 100) in the course of one hour. This, with intravenous injection of two and a half pints of saline solution in which was half an ounce of brandy, produced a pulse of good volume, with a rate of 100, *at the end of the operation. No twitching or* spasms occurred either during or after the operation. The patient lived for nine days.

I am, Sirs, yours faithfully,

Plymouth, April 27th, 1902. C. HAMILTON WHITEFORD.

To the Editors of THE LANCET.

SIRS,—The use of large doses of strychnine in the treatment of surgical shock was first advocated by me upwards of three years ago in a paper read before the Leeds Medico-Chirurgical Society and illustrated by a series of cases. A brief record of the paper may be found in THE LANCET of Dec. 17th, 1898, p. 1636. The paper was subsequently published *in extenso* in the *British Medical Journal* of Nov. 25th, 1899. Since that publication appeared I have used strychnine freely whenever death from shock has been threatening and more especially during operations for what may be conveniently termed "peritoneal catastrophes." I am in the habit of injecting 10 or 15 minims as a first dose, continuing to give 10 minims hypodermically whenever the pulse shows signs of failing. I have given 40 minims during an operation in this manner in a case of extreme collapse.

After four years' experience both in private and hospital surgical practice I can say that I have never once been able to detect the slightest sign of poisoning, either immediate or remote, in any case in which I have used strychnine. I can therefore only reassert my original statement that in conditions of extreme shock patients will tolerate very large doses of strychnine and that when given boldly under such circumstances it is a valuable remedy.

As I almost invariably use ether as an anæsthetic the antagonistic action of chloroform can scarcely be a factor in this toleration of the drug. Moreover, I have given large doses of strychnine in cases in which practically no general anæsthesia was used. The toleration of strychnine in the collapse following snake-bite was pointed out more than 10 years ago by Mueller, who advocated the use of the drug as an antidote, and cases in which very large doses have been given have been recorded from time to time. It was chiefly due to a knowledge of some of these cases that led me to apply the treatment in surgical practice. I am no advocate for giving dangerous doses of strychnine prior to operation where shock is not already present, although a reasonable dose by acting as a general respiratory and circulatory stimulant is an obviously rational preparation for a severe operation.

Until we have some explanation of this peculiar tolerance in shock it behoves us all always to realise fully the grave responsibility which we incur in pushing the drug to dangerous limits, even in desperate cases. At the same time the experience not only of myself but also of other surgeons has undoubtedly established the fact that these large doses can be used with good effect in cases of extreme shock and without producing symptoms of poisoning.

I am, Sirs, yours faithfully,

Bradford, April 26th, 1902. J. BASIL HALL.

To the Editors of THE LANCET.

SIRS,—That the large doses of strychnine advocated by Mr. Mayo Robson and Mr. C. Hamilton Whiteford are not entirely without danger I can testify from an experience I had when house surgeon in a provincial hospital. A boy, aged six years, was admitted at 6 P.M. with the history of having swallowed and then vomited the tin socket of a small Chinese lantern. On admission the boy seemed well and had no pain, but at 2 A.M. the following morning he became suddenly collapsed, with all the symptoms of perforation of the stomach. At 4 A.M. he was given five minims of liquor strychninæ hypodermically, was anæsthetised with chloroform and the abdomen opened; a small perforation was discovered on the anterior surface of the pylorus (this had evidently occurred some hours previously and had been temporarily closed by lymph) and closed with sutures. During the operation the patient's condition became extremely critical from heart failure, but five minims of liquor strychninæ were injected, the operation was rapidly completed, four pints of saline solution were transfused into the median basilic vein, and the patient left the operating table with a good pulse. At 8.30 the boy was seized with convulsions and rapidly passed into a condition of opisthotonos and died before chloroform could be administered.

I am, Sirs, yours faithfully,

Lincoln, May 5th, 1902. A. STANLEY GREEN.

INFANTILE SCURVY AND RICKETS.

To the Editors of THE LANCET.

SIRS,—In the letter which I wrote to you on "Unboiled *versus* Boiled Milk" and which you published in THE LANCET of June 29th, 1901, p. 1859, I pointed out that there was some alteration effected by the boiling which was deleterious to the nutrition, growth, and health of some of, and probably to some extent of all, the unfortunate infants who are "brought up" on this artificially prepared milk, as against milk in its natural state. I also pointed out that the same facts applied to that series of artificial foods prepared with sterilised or boiled milk, which are so excellent as temporary substitutes for "fresh" milk for a few weeks where, as on board ship, or in hot weather, or from illness, fresh milk is difficult to obtain or deteriorates before it can be consumed, and so disagrees. The same milk-defects also arise when the mother's milk has deteriorated from prolonged or over-lactation. The storm which my letter created made me raise the question in my own mind whether it was not expedient for me to consult an alienist.

The excellent paper which has appeared in THE LANCET of May 3rd, 1902, p. 1246, by Dr. George Carpenter has, however, set my mind at rest on that score, for he says, and I agree with him: "That a diet of sterilised milk, simple boiled milk, pasteurised milk, pasteurised percentage milk mixtures, peptonised milk, condensed milks, malted milks, desiccated milks, the numerous proprietary foods, and cereal gruels combined with the above milk preparations, each in turn or in combination, has produced scurvy in those prone to that disorder, though harmless in that respect to others." I only wish that he had completed the sentence which I have quoted by adding that where "fresh" milk is given to infants and young children infantile scurvy never arises and rickets rarely where the hygienic conditions of the child are as they should be.—I am, Sirs, yours faithfully,

CLEMENT DUKES, M.D., F.R.C.P. Lond.

Rugby, May 6th, 1902.

CHYLOUS HYDROCELE.

To the Editors of THE LANCET.

SIRS,—The following may be of interest owing to its rarity of occurrence. A Hindoo came into hospital with a large hydrocele which was not very translucent. On tapping the fluid was found to be milky in colour, suggesting at first that there might be some fistula of the testicle communicating with the sac and that the fluid was mixed with seminal fluid. On microscopical examination the field was full of fat droplets coated with an albuminous film in a clear liquid. There were one or two cholesterine crystals; no spermatozoa were present. I have searched a large number of recent large systems on surgery but I find no mention of this condition except in that of Holmes and Hulke (vol. iii., p. 480), who quote one or two cases from M. Vidal and from the Transactions of the Pathological Society of London, vol. xvi., p. 184. The fluid was unfortunately thrown away contrary to my orders, so that the specific gravity was not recorded.

I am, Sirs, yours faithfully,

J. RUTTER WILLIAMSON, M.B., Ch.B. Edin.

Mission Hospital, Miraj, Western India, March 20th, 1902.

THE APPROACHING ELECTIONS AT EPSOM COLLEGE.

To the Editors of The Lancet.

Sirs,—May I express the hope that those who have not already pledged themselves in favour of one or other of the candidates will carefully read the lists just issued and vote *only* for those whose husbands or fathers have themselves subscribed? Year *after year an urgent appeal is made to the* profession for greater pecuniary support and yet it frequently happens that the claims of some of those who have responded to these appeals in the past are ignored in the list of candidates recommended by the Council. It should, I think, be made quite clear in every possible way and upon all occasions *that subscribers to the College* have a *primary claim upon its* benefits should necessity arise and only when the dependents of past subscribers have been provided for will the claims of others be considered; I do not otherwise see upon what practical grounds the appeal can be made. This, I think, must be the view of many of my professional brethren. I do not know how otherwise to explain the very striking anomaly presented by this year's list, for of 55 candidates apparently only five were former subscribers!

I am, Sirs, yours faithfully,

London, May 5th, 1902. Life Governor.

THE GERMAN SURGICAL CONGRESS.

(From our Berlin Correspondent.)

(*Concluded from page 1283*)

Histogenesis of Cancer

Professor Gussenbauer (Vienna) said that his clinical experience had persuaded him of the parasitic nature of the cancer virus. He had endeavoured to study its action by taking a large number of microscopical sections from the tissues lying outside the borders of the growths where the virus was likely to have acted without producing manifest symptoms and he had discovered that a general proliferation of cells was present there.

Professor Kahlden (Freiburg) discussed the etiology of relapses in cancer. They, he said, might originate from parasites of the growth which had not been removed at the operation. They might also be caused by thrombosis of the lymphatic vessels or by direct infection. Inoculation of the healthy tissue by the instruments used during operation was also possible. The growth might also from the beginning develop at different places and at different times.

Dr. Petersen drew attention to the fact that the micro-organisms detected in cancer were always in symbiosis with the cells. Relapsing growths always arose from the epithelium of the organ first attacked, either as real relapses unconnected with the first growth, in some degree like a newly-formed tumour, or indirectly as a continuation of the original growth. A parasitic etiology was not yet established.

Dr Nöske (Leipsic) said that none of the parasites hitherto detected in cancer had been proved to have a causative relation to the disease. He had found Mr. H. G. Plimmer's corpuscles in non malignant growths.

Dr. Doyen (Paris) showed specimens of a "micrococcus neoformans" which was present in cancer, the number of the micrococci corresponding with the malignancy of the growth.

Cancer of Various Organs.

Professor Mikulicz (Breslau) said that apart from cancer of the rectum he had seen 106 cases of malignant growth of the intestines, of which 100 were cancer, five were sarcoma, and one was endothelioma. More than 80 per cent. occurred in men, the sites of predilection being the sigmoid flexure and the cæcum. They might be latent for a rather long time. When stenosis happened the prognosis varied according to the acuteness of the symptoms; in acute cases colostomy was the only available operation. Resection of the intestines was performed in 37 cases. In 21 cases the operation was completed at one sitting and among these patients there were nine deaths; in 16 cases he operated in two successive stages with only two deaths.

Dr. von Hochenegg (Vienna) reported that of 174 cases of cancer of the rectum operated on by him 30 remained free from relapse three years after the operation. He used the sacral method exclusively and operated in two stages, first performing a colostomy and eight days later the resection.

Professor Krönlein (Zürich) gave an account of 264 cases of cancer of the stomach of which 197 were operated on. In 251 instances he succeeded in obtaining a detailed history of the case from beginning to end. On an average the disease proved fatal after a duration of one year. Life was prolonged by gastro-enterostomy for about three months and by gastrectomy for about 14 months Of the latter cases 13 might probably be regarded as definitely cured, one patient surviving for eight years, one for four years, and the remainder for periods varying from three years to one year after the operation. Professor Krönlein, however, remarked that relapses after a comparatively long time were not rare, so that a definite cure must not be announced too soon. The results would be still better when operation for cancer of the stomach became more popular with the medical profession as well as with the general public. At present patients were sent to the surgeon as a rule in far too advanced a stage.

Abdominal Surgery.

Professor Körte (Berlin) gave details of 60 subphrenic abscesses originating from appendicitis, gastric and duodenal ulcers, gall-stones, &c In 41 cases a transpleural operation was performed, in 16 instances he made an incision through the ribs and in four cases a median incision. 66 per cent. of the patients recovered.

Professor Sprengel *(Brunswick) said that he had made a* collective investigation of 516 operations for appendicitis, of which 284 were performed during an attack, the result being 20 deaths. Of 232 patients operated on during an interval only two died. He strongly recommended operating early and very soon after the first attacks, before the peritoneum was likely to have become seriously affected.

Professor Roux *(Lausanne) warned his hearers against* operating during an attack of appendicitis; in most cases no harm was done by waiting for five or six weeks. When an operation during an attack could not be postponed owing to the state of the patient then a mere incision into the abscess was sufficient.

Dr. Doyen said that in general peritonitis he recommended early incisions and a "toilette" of the abdominal cavity without washing the peritoneum. Where paralysis of the intestines had developed a temporary colotomy was advisable.

Professor Friedrich (Leipsic) explained that in general peritonitis anaerobic bacteria were present and that the admission of air into the peritoneal cavity when incisions were made might destroy these bacteria.

Professor Kocher read a paper on Peptic Ulcers subsequent to Gastro-jejunostomy They were not always of traumatic origin but might occur after several months or even years owing to the action of the gastric juice on the jejunum. It was not yet ascertained whether this complication was more frequent after anterior or posterior gastro-enterostomy. Professor Kocher had once excised the ulcer, the intestine being adherent to the abdominal wall.

Professor Hahn said that if the frequency of this complication was the same after both anterior and posterior gastro-enterostomy the anterior operation should be performed to the exclusion of the other, because it allowed an eventual excision of the ulcer

Dr. Kausch said that if this complication were more frequent gastro-enterostomy would have to be abandoned for pyloroplasty.

Cryoscopy of the Urine.

Dr. Kümmell (Hamburg) drew attention to the value of cryoscopy of the urine as a trustworthy means of ascertaining the relative efficiency of the kidneys. Cryoscopy meant the determination of the freezing-point of a liquid. The freezing-point of normal urine was about – 0·56° C; if it rose slightly the function of the kidney was likely to be abnormal. The important conclusions submitted to the Congress last year by Dr. W. Kümmell and by Dr. Casper of Berlin had now been confirmed by the result of several operations.

Among the other papers read before the Congress mention may be made of those dealing with operations on the brain by Professor Rehn (Frankfurt), Dr. Thiem (Cottbus), and Dr. Saenger (Hamburg).—Papers were also read by Dr. de Quervain (Chaux-de-Fonds) on Acute Thyroiditis, by Professor Kuster on Œsophagotomy, by Dr. Tavel on Anti-streptococcic Serum, by Dr. Bunge on Talma's Operation, by Dr. Reerink on Plastic Operations on the Stomach.—On the evening of the first day of the Congress demonstrations with the diascope and the kinematograph were given —Dr. JOACHIMSTHAL showed photographs of the structure of the patella and Dr. PERTHES showed photographs of the feet of Chinese women.—The representation of Dr. DOYEN'S operations by means of the kinematograph was a remarkable spectacle. He showed the operation of trephining, a resection of the knee-joint, an ovariotomy, and finally his famous operation for the separation of the xiphopagous Hindoo girls. The different stages of the operation were quite visible though the small size of the photographic pictures made it impossible to discern the anatomical details.

Professor KÜSTER (Marburg) was elected President of next year's Congress.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Pasteur Institute at Kasauli.—Slight Decline in Plague Mortality.—Improvements in Madras.—Dengue Fever in Rangoon.—Model Dwellings in Calcutta.

THE work done at the Kasauli Institute has been satisfactory and successful beyond expectation. During the past eight months 352 persons have been treated for bites of rabid animals Of this number 126 were Europeans and 226 were natives. There were eight British officers and 48 British soldiers, besides 28 men of the native army and there were 61 European civilians and 198 native civilians. Since the institution was opened in August, 1900, practically every European who has been bitten by a mad animal has attended for treatment so that no increase of patients from the European population of India is expected, but the institution is rapidly gaining in popularity amongst the natives. It is very satisfactory to find that every European patient has been successfully treated. Natives as a rule are severely bitten and often by mad jackals and they delay in their attendance for treatment. Notwithstanding this the failures among natives amount to only 0 8 per cent These results will be considered eminently satisfactory and it is expected that this year's results will surpass those of the Paris Institute. As the Government necessarily saves the cost of sending British soldiers to Paris it is anticipated that a larger vote of money will be now granted.

The plague figures for the week have been delayed but local returns show a general decline. Karachi is still severely oppressed but there are signs of diminution both in Bombay and in Calcutta. In neither city has the outbreak been so severe this season and in Bengal it has been quite abortive in character. In the circumstances it is impossible to draw any conclusions as to the success of sanitary measures. Bombay must have been pretty well soaked with disinfectants and Calcutta has absorbed tons of perchloride of mercury. The difference between the two cities appears to be that in Calcutta except for the plague the population seems to be fairly healthy, whereas in Bombay over and above the plague there is a very high mortality.

Those who know Madras will be glad to hear of the improvements which are to be made in Black Town. The old general market is to disappear and it will be converted into a recreation ground and garden.

Dengue fever is still raging in Rangoon and one fatal case has occurred.

The opening of a block of model dwellings for the poor in Calcutta is an experiment of great value. The present poorer dwellings are mostly single-storeyed and cover a large area. In this way they differ very greatly from the *chauls* of Bombay. The block in question contains about 67 rooms, each 12 feet square; it is well ventilated, well paved, and provided with satisfactory sanitary appliances. The difficulty seems to be that masonry dwellings cannot be constructed to provide for the requirements of sanitation as well as to furnish an adequate interest on the money invested, and the rents, therefore, may prove prohibitive to the very classes for which these dwellings were intended. Moreover, even if occupied there is the danger that the crowding may become as excessive as it is in Bombay where between four and five people on the average occupy single-room tenements At present even in the wattle-and-daub mud huts, which admit considerable ventilation, the crowding at night-time, especially in the cooler seasons, is excessive and the air is very offensive. The present venture is a private one on the part of some wealthy natives. As habitations these model dwellings are excellent and if they should not prove financially successful I still think that the corporation ought to provide further blocks in the public interest. In the *bustis* of Calcutta the surroundings of the huts are so filthy that overcrowding greatly intensifies the insanitary conditions.

Calcutta, April 17th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Sanitary Congress in Manchester.

THE jubilee of the Manchester and Salford Sanitary Association was celebrated very successfully on April 24th and 25th. At the opening meeting the Lord Mayor of Manchester (Mr. Alderman Hoy) cordially welcomed the members and, what is important and encouraging for the future, bestowed on the association the municipal blessing. The Bishop of Manchester, as President, delivered an inaugural address marked by the sound robust sense characteristic of his utterances. Dr. Ransome gave an interesting historical sketch of the origin and work of the association, while Sir James Crichton Browne held the audience wrapt in the closest attention during his most eloquent and picturesque address on light and sanitation. In the afternoon Mrs. H. J. Tennant, late chief woman inspector of factories, read the opening paper in the afternoon on Women's Work in Sanitary Reform, and said that in the prevention of infant mortality due to ignorance or neglect on the part of parents there were "splendid possibilities for women workers." In the discussion which followed Mr. D. B. Hewitt, chairman of the Public Health Committee of the Cheshire County Council gave a lamentable account of the mortality among infants, 200 to 300 per 1000, in some of the smaller towns of Cheshire. Dr. H. Simpson emphasised the importance of practical educational work in sanitary reform and Sir J. Crichton Browne spoke of the importance of women's work in bringing home to the people the need of obedience to the laws of health. Dr. A. Newsholme next read a paper on Vital Statistics and their Relation to Sanitary Reform. This was followed by one from Mr. Horsfall on the Housing Question in which he gave interesting details of the arrangements in German towns. The ideal city would, no doubt, be a less unlovely and a healthier one than any we now have, but the cost would place it at present beyond the limits of the practical. The interest in the meetings was well maintained and a good and attentive audience met on the 25th to hear Sir William Broadbent's clear and philosophical address on the Prevention of Tuberculosis. He was followed by Professor A. Bostock Hill who read a valuable and suggestive paper on the Relationship of Voluntary Effort to Constituted Authority in Promoting Sanitary Reform. After luncheon a paper was read for the Earl of Meath, who was unavoidably absent, on Physical Training, the necessity of which is evident to those who see the rapid deterioration of race going on in our large towns. A paper was also read for Mr. Ralph Neville, K.C., on Garden Cities, and the literary part of the conference was closed by Dr. J. Niven, medical officer of health of Manchester, who contributed a paper on the Economics of Health. The conference excited a good deal of interest and it is to be hoped that it will lead to an increase of membership and thus yield increased power for good. On the Thursday evening the Lord Mayor and the Lady Mayoress held a reception at the town hall and on the Friday evening a banquet took place at the Queen's Hotel which was presided over by Professor J. Dixon Mann, the chairman of the committee of the association.

Care of Defective Children.

The first special school for weak-minded children in Manchester was opened about a month since in Hulme. An inspection of 39,600 board school children made three years ago showed that 525 seemed more or less unable to compete with other children in the ordinary classes. Of the 525, 214 were "dull and backward," 276 were "mentally feeble," four were "deaf-mutes," while six were not so backward as to need special attention. At first the school board started special classes. Now there is a special school in Hulme, there will soon be a second school in North Manchester, and a third school will be required shortly. School training is only part of the work, and after school days care is needed. Helplessness falls an easy prey and the story of weakness may be carried into another generation. This points to the remedy being permanent, such as retention in special homes where they may live securely and do more or less useful work. The Lancashire and Cheshire Society for the Permanent Care of the Feeble-minded has made a beginning of this work. A boarding school for 15 boys and one for 15 girls have been built at Sandlebridge near Alderley, and this will after a time be completed by the addition of two more schools—for adults and for infants. Salford, however, can claim priority over Manchester in making provision for "deficient children," having had a school for them which began its work more than two years ago. The building is inconvenient and a graveyard serves as a playground, but the teaching is efficient and in June the children are sent to Mellor in Derbyshire for bracing country air for a week. The teaching in the Manchester school is individualised as much as possible. The brain work comes in the morning while the children are freshest. There are Scripture reading and some simple normal lesson. A good deal is done in the way of "nature teaching"—e.g., in one class a visitor found the children eagerly examining a bottle of tadpoles and making remarks thereupon. They are talked to on matters of general interest. Few of them can speak well and daily lessons in articulation are given. In the afternoon the training is on kindergarten lines for they require training of their senses and of their muscles much more than do ordinary school-children. There is a good deal of play and pleasant drilling. In this way something is done to improve the lot of these unfortunate ones.

Recruiting in Manchester

If anything were needed to show the serious deterioration going on as to the physique of our town population the recruiting returns for Manchester would probably serve. Some three years ago it was stated that of 11,000 men examined—in round numbers—only about 3000 were fit for the service. In 1900 the number of applicants examined was 12,235 and of these 4030 were fit to serve. Within the last 12 months 11,896 men were examined and of these only 3076 were accepted for service. Those rejected were for the most part so ill developed and poor in physique that it was impossible to take them though the authorities were anxious to accept as many as possible. The standard is now lower than it has ever been. A minimum chest measurement at full expansion of 33¼ inches and a minimum height of five feet three inches are sufficient. The Manchester applicants for enlistment are many of them youths of 18 or 19 years of age and are average specimens of those living in the poorer quarters of the city. It is said that instead of 33¼ inches the chest measurement of many young fellows of the age of 18 years is only 28 or 29 inches and they are undersized in proportion. The recruiting officers believe that one principal cause for this miserable want of physique is the habit of cigarette-smoking by youths. "They come to us with their fingers stained with cigarettes and nearly all of them are suffering more or less from palpitation of the heart," and the looked-for remedy is considered to be compulsory physical training in all elementary schools. Cigarette-smoking, no doubt, is an important factor, but not the only one, while its influence is undoubtedly much exaggerated. Born and brought up in the vitiated atmosphere of a town slum, in a crowded and generally miserable and uncleanly tenement, with all inlets for the outer air carefully closed at nights, unsuitably fed as an infant, and insufficiently and often unwholesomely fed when he ought to have been a growing youth, the stunted, ill-developed figure and the feeble muscles of this product of one of the phases of our civilisation cannot cause surprise. Nor can a high morale be reasonably anticipated. There is a great deal said on the need for technical education, but an even greater need for the nation is that our boys and girls shall grow up with sound bodies, when there will be good chance of their having sound minds.

May 6th.

WALES AND WESTERN COUNTIES NOTES

(From our own Correspondents.)

The Prevention of Spitting

It already has been stated in The Lancet[1] that a by-law prohibiting spitting can be made by a county council in fulfilment of the powers given by the Local Government Act, 1888, to make by-laws for "the good rule and government of their county." The County Council of Radnorshire has now adopted a by-law identical with that which is in force in Glamorganshire and which entails a penalty of £5 upon any person who spits upon the floor of a public carriage, church, school, public hall, &c. There was practically no opposition to the adoption of this by-law by the county council and one speaker urged as a reason in favour of the proposal that many consumptives came to the Welsh Wells and that if people were not suffering from consumption spitting was a dirty habit and a small fine would do them good.

Foreign Lunatics at Seaports

The Asylums Committee of the Cardiff Corporation is concerned at the increasing cost to the corporation of maintaining foreign lunatics. The average annual cost during the past five years has been £317, but it has increased from £109 in 1898 to £636 in the present year. There does not appear to be any connexion between this increase and the number of foreign vessels putting in to the port, for in 1897 the number of such vessels calling at Cardiff was 3174, while in 1901 only 2829 put in. The Asylums Committee has decided to bring the matter before the authorities of other seaport towns with a view to securing joint action in a representation to the Lunacy Commissioners in order, if possible, to secure an alteration in the present law.

Madame Patti at Brecon

A concert in aid of the funds of the Brecon County and Borough Infirmary is to be given in September next by the Baroness Cederstrom (Madame Patti). The infirmary was founded in the year 1833 and contains 16 beds. Madame Patti has once before, in 1885, given a concert in support of the infirmary.

The Prevention of Tuberculosis

When the South Wales and Monmouthshire Branch of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis was inaugurated in Cardiff last year one of the avowed objects of the branch was the establishment of a sanatorium and at a meeting held on May 3rd it was decided to take immediate steps to promote the erection of such an institution to serve the needs of Glamorganshire and Monmouthshire. These two counties have populations of 880,000 and 300,000 respectively. In the former county, where 7 per cent. of all the deaths registered are due to consumption, the phthisis rate is 1·2 per 1000 and there are about 1000 deaths annually from the disease. In Monmouthshire the phthisis death-rate of 1 per 1000 is among the lowest in the kingdom, and there are about 300 deaths from phthisis annually, or a number equal to 6 per cent. of the deaths from all causes. At the meeting referred to Dr. W. Mitchell Stevens pointed out that the lot of the poor consumptive was a most unenviable one, for since consumption had been recognised so strongly as being an infectious disease the general hospital was closed against him. Dr. Stevens urged that not only the early, but the more advanced, cases should be looked after as it was from these that the danger of the spread of infection specially arose.

Sanitary Condition of Merthyr Tydvil

Until less than 30 years ago Merthyr Tydvil was by far the most considerable town within the principality of Wales and it is only during the past quarter of a century that it has been outstripped by Cardiff, where in 1851 the population was only 18,000 while in Merthyr it was nearly 47,000. At the last census the population of Cardiff was 164,000 and that of Merthyr was 69,000. The insanitary condition of Merthyr, with its resultant high death-rate, has been the subject of many inquiries by inspectors of the Privy Council and of the Local Government Board and as a result of their reports and recommendations the sanitary authority has of late years bestirred itself to improve the condition of the town and has thus endeavoured to lower the rate of mortality. Dr. William Williams (the medical officer of health for the county of Glamorgan), in his sanitary survey of the county, states that as long ago as 1854 Dr. William Kay, who was temporarily appointed health officer in 1852, concluded a report thus: "The unhealthiness of Merthyr Tydvil is attributable to local and self-created conditions, the vicious construction of houses, the inadequate water-supply, the absence of drainage, and the necessary consequence—accumulations of filth, atmospheric impurity and excessive and fatal prevalence of disease." As an index to the activity displayed by the urban district council and its predecessor the local board of health it is of interest to quote from the recently issued report to the district council of the present medical officer of health, Mr. D. J. Thomas, in which he says: "You have one of the best water-supplies in the kingdom. Not only is the supply good in quality but there is a sufficiency of it. You have spent vast sums of money to obtain a system of sewage disposal which is at once clean and efficient." The death-rate, however, is still high. In 1901 it was 25·9 per 1000, and in one district of the town—Dowlais—the death-rate was over 33 per 1000, although it is situated at an elevation in some parts of 1760 feet, while nowhere is it less than 800 feet above sea-level. During the past 10 years the death-rate of Merthyr has never been below 20 per 1000 and in one year it was over 30 per 1000. The infantile mortality rate in 1901 was equal to 261 per 1000 births. In Mr. Thomas's opinion there are two causes operating towards the high death-rate which overshadow all others—the conditions under which the poorer people are housed and the ignorance displayed by mothers in the rearing of infants.

---

[1] The Lancet, March 22nd, 1902, p. 851.

Verdict of Manslaughter for Improper Feeding of a Child.

At an inquest held on May 1st at Bristol a coroner's jury returned a verdict of "Manslaughter" against a woman whose child had died from convulsions and bronchitis accelerated by improper feeding. It was stated in the course of the inquiry that the child had been fed upon condensed skim milk, which cost 2½*d.* per tin, and upon boiled bread.

Small-pox.

There are now two cases of small-pox at Aberdare. There are no fresh cases in the Rhondda Valley; the man who was infected from Aberdare died on May 1st. There is a case of the disease in the Newport Hospital, the patient being the engineer of a steam yacht from which a case had been removed at Gibraltar.

Vaccination at Helston.

At the meeting of the Helston (Cornwall) Board of Guardians held on April 12th it was decided to open stations for the purposes of revaccination. It was reported that the cost of revaccination and the primary vaccination of adults for the past three months amounted to £129. A communication was read from the Local Government Board in answer to a letter from the guardians drawing attention to some vaccination posters issued by the Helston Borough Council as the local sanitary authority, and to which the guardians objected as they considered that the posters had been signed by the public vaccinator. The Local Government Board, however, stated that the notices could not be regarded as signed by the public vaccinator, and that it did not feel called upon to make any observations upon the matter.

May 5th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Aberdeen University.

THE session commenced on April 29th. The Senatus met in Marischal College on April 30th, Professor Stephenson presiding in the absence of Principal Lang. The business was of a routine nature. The Court agreed to change the date of meeting from Saturday to another day of the week as an experiment. An address in German was received from Professor Virchow of Berlin in acknowledgment of the congratulations which the University had presented to him on the occasion of his eightieth birthday. It will be remembered that in addition to its congratulations the Senatus conferred on Professor Virchow the honorary degree of LL.D.

The Admission of Medical Students to Aberdeen University.

A new by-law regulating the admission of medical students to Aberdeen University has come into force whereby no student under 16 years of age is admitted. A certificate of birth has to be produced by applicants for registration.

Obituary.

Jeannie Charlotte MacLeod, M.B., Ch.B., LL.A., resident physician and surgeon at the Royal Hospital for Sick Children, Aberdeen, died there suddenly on May 2nd. She graduated only last month at Aberdeen University and entered on the above appointment one week before her death.

May 6th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Convocation of the Royal University of Ireland.

ON May 9th the contest will take place for six representatives of Convocation on the Senate of the Royal University of Ireland. There are nine candidates in the field, and considerable interest is being taken in the fight which is being waged with great vigour. At a meeting of the Roman Catholic members of Convocation residing in Dublin on April 27th in the Catholic University it was unanimously decided to recommend the Roman Catholic members of Convocation to vote for two candidates—Mr. M. Drummond, M.A., K.C., of Dublin, and Dr. J. Cotter of Cork—both of whom are Roman Catholics. The Royal University Graduates Association, whose headquarters are in Belfast, has issued a circular in support of Mr. A. Anderson, M.A., President of Queen's College, Galway, Dr. Walton Brown (Belfast), Mr. E. Cuming, M.A. (Dublin), Rev. Professor Leitch, D.Lit. (Belfast), His Honour Judge Shaw, LL.D. (Dublin), and Professor Sinclair, M.D., of Belfast. This association in its circular urges that the question of extern examiners is the burning one in the present contest, their appointment being of cardinal importance in all the faculties but of vital importance in the medical faculty. It is opposing Sir W. Thomson, M.A., M.D. R.U.I., another candidate living in Dublin whom it regards as not sound on this question.

Royal Commission on University Education in Ireland.

The next meeting of this Commission is to begin in London on May 20th and it is believed that the following among others will be examined: Dr. Anthony Traill, Fellow of Trinity College, Dublin; the Right Hon. Lord Justice Fitzgibbon; Rev. Professor Todd Martin, D.Lit.; Archbishop Walsh; and Mr. F. H. O'Connell, M.A. After a few days' sittings the Commission will sit again in Dublin in June when the final report will be drawn up.

Royal Victoria Eye and Ear Hospital, Dublin.

Referring to some statements which have appeared in letters to public journals suggesting that extravagance is not infrequent in the management of hospitals and that the subscribers have a right to know precisely what is done with their money, the council of the Royal Victoria Eye and Ear Hospital, Dublin, at its last meeting requested the honorary president and honorary treasurer to court the fullest investigation from the public as far as its institution was concerned. A very interesting letter appeared accordingly in the *Irish Times* of April 26th, signed by Lord Monk and Mr. Mark Perrin, giving some details as regards the expenses of management, diet, &c., of the hospital. Among other statements the letter contains the following: "Our patients get food of the best quality, well cooked, and as much of it as they can eat; your correspondent and others will be surprised to learn that the cost of this ample, good, and comfortable dieting is very slightly over 6½*d.* per head per day, the entire cost of maintaining a bed for one year being £40 1*s.* 6*d.*, which includes drugs, foods, proportional cost of nurses' and servants' wages, fire and light, rent and taxes, laundry, and salaries." It occurs to me that if every hospital in Dublin supported by charity would furnish such a satisfactory record as the above there would be no further suggestion of extravagance or mismanagement in the public press. Since the above was written the admirable and business-like statement of Lord Monk has borne fruit. On May 1st it was announced in all the public journals that an anonymous donor had offered through his Grace the Most Rev. Dr. Peacocke, Archbishop of Dublin, the generous contribution of £1000 towards the building fund of this hospital on the condition that £4000 more be subscribed to the fund by Nov. 1st next. The council of the hospital has gratefully accepted this kind offer.

The late James Irvine, L.R.C.P. Edin., L.F.P.S. Glasg.

I regret to announce the death of Mr. James Irvine, which occurred at his residence, Lonsdale, Belmont, Belfast, on April 29th. His death was not unexpected as he had for some time been in ailing health and was unfit for work. As a student Mr. Irvine attended Queen's College, Belfast, and in 1867 he obtained the L.R.C.P. of Edinburgh and the L.F.P.S. of Glasgow. Mr. Irvine was dispensary medical officer of Castlereagh, No. 3 district, for 30 years and during his long career enjoyed the confidence and gained the esteem of a large *clientèle* A great favourite, his kindness, geniality, and sympathy gained him a large circle of personal friends Mr Irvine was buried on May 1st. He leaves a widow, four daughters, and two sons, one of whom, Mr Hugh R. Irvine, succeeded his father a few years ago when through failing health he was obliged to resign his dispensary

Small pox in Belfast

On April 30th a woman who had come from Liverpool on April 17th was admitted into the Union Hospital and on the following day symptoms of small pox appeared The case is a severe one The patient from Glasgow, who developed the disease on coming to Belfast, has recovered.

The Belfast Hospital for Sick Children.

A collection, organised by the Belfast United Trades and Labour Council, was made on May 3rd on behalf of the Belfast Hospital for Sick Children when a large sum of money was the result

Health of Belfast

The annual death rate between March 16th and April 19th was 22·7 per 1000, while in the corresponding part of last year it was 27·4 The death rate is lower than in the report for the previous month and is specially low in the case of zymotic disease

Benn Ulster Eye, Ear, and Throat Hospital

At the annual meeting of the friends of this hospital, held on April 24th, it was reported that during the past year the number of patients under treatment in the hospital (of whom 463 continued in attendance from the previous year) was 1992, while 212 were received as intern patients The board of management had decided to increase the charge of intern patients from 10*s* to 15*s* per week, with the result that the debt of the institution, which was £567 15*s* 8*d* at the beginning of the year, was reduced to £412 16*s* 8*d* at its close The total income for the year was £670 8*s* 1*d*, and the expenditure was £715 9*s* 1*d* Dr W A. McKeown, surgeon to the hospital, said that his experience in Belfast and in Ulster in the last 20 years enabled him to say in relation to the work done by that and other hospitals, that the majority of the cases of diseases in young persons originated through defective hygienic conditions He referred to the great help given to him in the work of the hospital by his experienced assistant, Dr W M Killen.

Londonderry Eye, Ear, and Throat Hospital

At the annual meeting of the friends and supporters of this hospital, held on April 24th, it was reported that there had been 1368 extern and 94 intern patients during the year ended March 31st, 1902. There had also been 1037 dental cases under the charge of Mr E. Donaldson and Dr W B Hunter This hospital is doing excellent work for patients in Derry and the North west of Ireland It was decided to provide an apparatus for administering anæsthetics to the dental patients.

Down District Lunatic Asylum

At a meeting of the committee of management of the Down District Lunatic Asylum held on April 19th, it was announced by the resident medical superintendent that the contractors had commenced the work of the erection of the iron isolation hospital which will be a very necessary and most useful adjunct to the asylum.

North of Ireland Branch of the British Medical Association.

The spring meeting was held in the Belfast Museum on April 24th, the President, Dr J S Darling (Lurgan) being in the chair The president read notes of a case of Pernicious Anæmia developing in six weeks. Dr J St. Clair Boyd and Dr J Tennant read notes of cases of Extra uterine Fœtation. Professor T Sinclair reported upon a case of Simultaneous Appendicectomy and Transverse Colectomy ending in recovery Dr A. Dempsey showed specimens removed from two cases of Extra uterine Fœtation successfully operated upon. Mr Robert Campbell read notes of a case of Acute Intestinal Obstruction by a Band in an elderly woman and showed a specimen of a Peculiar Body in the Vermiform Appendix. Dr W Calwell read notes of (1) a case of Tetany in Dilatation of the Stomach, (2) a rare form of Relapse in Typhoid Fever and of a second attack after a few months interval; and (3) on the Nitro-propiol Test for Sugar in Urine based on 100 Examinations.

PARIS.

(FROM OUR OWN CORRESPONDENT)

Rats and Plague

M GAMALEIA of Odessa forwarded an interesting note to the Academy of Medicine which was communicated to that body by M. Proust. M. Gamaleia has found that important differences exist between the rats found in sewers and those found in houses Sewer rats are very refractory to plague, or, at least, if they do contract it from eating carrion, they do not infect other rats House rats, on the contrary, are those which are found also on board ship They contract plague very easily and infect their fellows through the intermediary of fleas M Proust considers that the fact that the continent of Europe possesses more sewer rats than house rats is the reason why plague, starting from a port, spreads only slowly through the country, whereas it will spread from one ship to another very rapidly

The Benefits of Tobacco

Heretofore scarcely anything but the dangers of the use of tobacco have been insisted upon. But now a physician, Dr Dumon, in a thesis for the degree of Doctor of Pharmacy, points out that tobacco is of great use to medical men and others who come into contact with those suffering from influenza, diphtheria, and tuberculosis Dr Dumon has studied the action of tobacco smoke upon the various organisms found in the cavity of the mouth and has come to the following conclusions Tobacco has no effect upon the development of the germs of typhoid fever or tetanus, but it greatly retards the growth of the bacilli of influenza, of diphtheria, and of tuberculosis. These experiments were made with definite cultures and Dr Dumon is able to assert that the vapours of nicotine and pyridine which are produced by the burning of tobacco do render the buccal cavity more or less aseptic The same fact has been noticed by dentists Possibly, however, this advantage is somewhat counterbalanced by the chronic intoxication of the nervous system which is produced by smoking and by the irritation of the naso pharynx which it sets up.

The Reorganisation of the Paris Hospitals

The question of the reorganisation of the Paris hospitals has been under consideration for some three years Many of the hospitals are by no means in accordance with modern requirements and should be pulled down But, naturally enough, the enormous expense which such destruction and construction would involve stands in the way The plan first proposed by the Prefect of the Seine in 1895 involved an expenditure of from 57,000,000 to 75,000,000 francs, according as to whether brick or stone were employed. The Municipal Council considers that to finish the three children's hospitals now building, to erect nine other new hospitals, and to pull down the old ones would require an expenditure of 105 000,000 francs This figure, however, is too high M Lefevre, who has drawn up a report on the matter, proposes to rebuild on the sites which they now occupy the following hospitals. the Pitié, the Cochin the Ricord, the Broca, and the Broussais, as well as to pull down the annexe of the Hotel Dieu He further proposes to rebuild one of the contagious hospitals and three general hospitals, to build a large central wash house and laundry, to enlarge the Brevannes and the Rochefoucauld establishments, and to put the remaining hospitals in thorough repair These works would require an expenditure of 75 000 000 francs The Municipal Council recoiled from this enormous sum and the plan was rejected M. Mourier on the part of the Assistance Publique, then brought forward anew the proposal of M Lefevre, with some modifications as follows (1) to rebuild on their present sites the following hospitals—the Cochin the Ricord, the Broca, and the Broussais, and to increase the total number of beds to 451, (2) to rebuild on different sites the following hospitals the Pitié, the Laennec, the Charité the Beaujon, and the Aubervilliers, with 557 additional beds, (3) to enlarge the annexe of the Hôtel Dieu and not to pull it down; (4) to build a new hospital for children suffering from tuberculous disease of the bones, (5) to enlarge the Hérold Hospital and that for Sick Children, (6) to enlarge the Brevannes and Rochefoucauld establishments so as to make 900 new beds, (7) to improve the wash houses and laundries, (8) to do away with the present central dispensary and to rebuild it at Ivry, and (9) to put the remaining hospitals into thorough repair By this scheme nearly 2000 new beds would be established, of which number 1208 would be purely hospital beds. The total cost would be 83,000,000 francs, of which sum 29,000,000 francs would be provided by the sale of sites set free by the demolition of existing buildings.

May 6th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Cholera in the Hedjaz.

IT is extremely probable that all the different epidemics of cholera which have reached Egypt since the first visitation in 1831 have invariably been transmitted to this country from Arabia, the conveying hosts on most, if not all, occasions having been pilgrims returning from the holy places. Egypt is therefore always much interested in the progress of the disease in Mecca and Jeddah. It appears that the first cases occurred in Mecca about Feb. 20th of this year, but it was not until March 5th that the disease was officially declared to be cholera. Unfortunately for those who have to control the hordes of the returning faithful the pilgrimage to Mecca this year has been an extra large one, and it is calculated that about 40,000 of the pilgrims have come from northern countries. The present effort of the Egyptian quarantine authorities is to prevent all pilgrims from entering Egypt by any other way than that of El Tor, and also to take care that while at El Tor every pilgrim is thoroughly examined and is prevented from pursuing his journey towards Europe or into Egypt until he is considered to be incapable of carrying cholera with him. To prevent clandestine landing on the Red Sea coast from native boats Government steamers and land patrols are always watching, while the Suez Canal is being guarded by its own agents and by coastguard police.

The Camp at El Tor.

Boats from Suez take about 12 hours to reach El Tor, which is situated 120 miles to the south of Suez on the eastern coast of the Arabian Gulf. When the steamers conveying pilgrims reach El Tor the passengers disembark into large boats which are towed to three disinfecting stations. Each of these stations is divided into two parts, for men and for women The clothes and luggage of each pilgrim are then put into sacks which are placed in the disinfectors, where they are subjected to a heat of 120° F. for 20 minutes. Any articles which would be spoilt by this heat are dipped into a sublimate solution. The steamer itself is thoroughly disinfected and the pilgrims themselves are conducted to a dressing-room connected with a bath-room where they have the choice of a cold or hot douche or a cold or hot sea-water bath. They are then moved on to another room where they join their clothes which have in the meantime been disinfected and where they are visited by the quarantine medical officer and a passport clerk. As everything is now done methodically about 100 pilgrims pass through each station every hour and in times of pressure the electric light allows the work to be continued by night. The pilgrim and his luggage are then conveyed by a local railway to the section of the camp destined for their accommodation. Each of these sections is a fenced-in enclosure 200 yards long and 50 yards wide on which there are standing 100 tents, each capable of sheltering six pilgrims, besides the tents of the medical officer and the sanitary police, the store, the restaurant, and the latrines. The medical officer visits each pilgrim twice a day and despatches any pilgrims who are sick to hospital at once. Cholera quarantine lasts for 15 days, but if a case occurs during the quarantine the pilgrims of that section are kept until 15 days have elapsed since the last case of cholera in their section. Egyptian pilgrims who have no long sea voyage to undertake after their emancipation are kept for 18 instead of 15 days. The camp contains 40 sections of which only the 20 intermediate ones are occupied, thus providing accommodation for 12,000 pilgrims at a time. Each section is complete in itself, is strictly isolated from the rest of the camp and is surrounded by a cordon of soldiers, and the camp is furnished with electric light and telephones. The stores are sold at a fixed tariff and the Government provides destitute pilgrims of all nationalities with two meals a day. This description refers to healthy pilgrims, but the moment one is discovered to be diseased he is removed to a hospital according to the nature of his complaint. One hospital is for surgical cases entirely, another for suspicious cases under observation, another for contagious disease, and yet another for cases of ordinary disease. The arrangements this year are certainly better than they have been on former occasions and it is to be hoped that the quarantine authorities will succeed in arresting all cases of cholera at El Tor, thus preventing the disease from being transmitted into Europe or into Egypt. In spite of all that has been written about it in former years the steamers conveying pilgrims are still fearfully overcrowded; one at the beginning of this month conveyed 1514 Russian pilgrims from Jeddah to El Tor and another steamer carried 1560 to the same port. Each of these arrived at El Tor with cholera on board.

The Pilgrimage of 1901.

To go back to last year for a moment it is satisfactory to point out that whereas the general mortality in the camp at El Tor was 0·64 in the case of non-Egyptians it was only 0·06, or 10 times less, in the case of Egyptian pilgrims. Moreover, the number of pauper pilgrims from Egypt was only 61, or less than 1 per cent., of the total number of paupers during the year. On the other hand, out of a total of 18,900 foreign pilgrims no less than 6000, or 31 per cent., had to be fed at the expense of the Egyptian Government. The new rules for controlling the Egyptian pilgrims have been on trial now for three years and have answered so well without any friction that it is a profound pity that Turkey, Russia, and other countries do not adopt similar means to prevent paupers from attending the pilgrimage. The most important of the Egyptian rules are: (1) that no pilgrim is allowed to leave Egypt unless he is provided with a passport, and he cannot obtain this passport until he has deposited 32*s*. to pay for his disembarkation at Suez and his quarantine expenses; (2) that each pilgrim must have a return ticket the steamer, and that the steamer company must satisfy Egyptian Government that they can guarantee the re journey of all their passengers; and (3) that all pilgr landed at Suez must give their addresses to the local sani authorities who are thus able to trace them to their hor Many stringent regulations have been enforced about steamers carrying Egyptian pilgrims. Besides sani regulations the number of pilgrims which each vesse authorised to carry is painted in large letters on the sh side; each vessel is inspected by Government officials, £2000 caution money is deposited by every compan which authority to carry Egyptian pilgrims is given.

Cairo, April 28th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Municipal Control of Therapeutic Serums.

DURING the past year there have been—notably at Louis—some lamentable accidents from the use of diphth antitoxin manufactured by city boards of health which excited a certain amount of distrust as to the meth employed by such bodies. A movement in favour Government control has accordingly been initiated. while no objection has been brought against the adop of this plan a decidedly adverse sentiment has manifested against the system in force at the New City Board of Health. This board for some consider time has been accustomed to sell its therapeutic ser thus competing with private manufacturers The B of Health of New York City has gained a deserv high reputation for the good work which it has acc plished and it has been felt and expressed by physicians that by selling any of its products it not becomes tainted with commercialism but goes outsid own province and restricts its power of acting in the interests of the health of the community at large. On 17th a deputation of pharmacists, physicians, and ot opposed to the sale by the New York Board of Healt antitoxin and vaccine virus had an interview with the m (Mr. Low) for the purpose of protesting against this co and of endeavouring to prevail upon him to put a stop to custom. The petitioners were represented by counsel who presented a memorial signed by more than 1000 persons and who stated the condition of affairs to the mayor. The New York City Board of Health contends that only the surplus stock of virus is sold but when a profit of $20,000 (£4000) is made in one year, as in 1901, it would seem that the commercial side of the question is at least one of the objects in view. The and a glance at the balance-sheet included in the council's report for 1899 and 1900 will show that its resources are small and are administered economically, while it must be plain to all that an increased income means the possibility of an enlarged sphere of activity. Turning to the body of the report referred to for information we find an exhaustive record of work done by the council and of matters affecting the subject in which it interests itself. As an example of its operations we may call attention to a table in which 4927 cases are described as "central office cases"—that is to say, cases in which the inspectors of the council examined premises with regard to which complaints had been made to it. These cases were examined in one year, 1899, and 1607 of them were during the course of the year "dismissed as remedied," while 2250 were "dismissed as trivial or no defects," from which it will be evident that the council on the one hand is able to insist effectively where remedy is needed and that on the other hand it proceeds in a reasonable spirit and does not condemn where it finds no substantial fault. The balance of the cases in the list we quote from were carried over to the following year, and, indeed, the work of curing the evil arising out of the congested state of London is not a task that can be rapidly completed either as a whole or in individual instances. It may take many months, even years, to rouse a public authority to a sense of its duties to discover who is the proper person to be made liable for the defective drainage of a slum dwelling. And when he is found more time is required to bring home his liability to him before a magistrate, while he has then to commence the necessary work of sanitation.

One of the important legal points to which the Mansion House Council calls attention is the question of the landlord's liability to compensate a tenant under Section 75 of the Housing of the Working Classes Act, 1890, where he has ostensibly contracted himself out of his liability. The section in question decrees that "in any contract for letting for habitation by persons of the working-classes a house or part of a house, there shall be implied a condition that the house is at the commencement of the holding in all respects reasonably fit for human habitation." This in effect puts the letting of an unfurnished house or rooms to a working man on the same legal basis as the letting of furnished premises. It is an important section for working men to be aware of and for those interested in the public health to enforce. In one case recorded in the Mansion House Council's report a landlord was sued under this section for injuries received by the plaintiff owing to the dilapidated condition of a flight of steps and in this instance the landlord had judgment given against him. In another similar case, however, which the council considered, it was met by the fact that the complaining tenant had apparently acquiesced in a condition inserted in his rent-book, by which the landlord was freed from all liability imposed on him by the section in question. It will be observed that the section only speaks of an implied condition, and, as a rule, no doubt, an express condition overrides an implied one, so that we are not surprised to find that the opinion of counsel taken by the Mansion House Council was, on the whole, against the possibility of rendering a landlord liable in such a case. In this view the Mansion House Council, the Local Government Board, and the London County Council appear to agree, with the result that although the last-named body deems that legislation is desirable to prevent the landlord from "contracting out" the landlord who is astute enough to do so will probably for the present continue to protect himself, and as his tenants will be persons anxious to find house-room, and ignorant for the most part of their rights, he will probably succeed in doing so. In calling attention to defects such as this in the laws affecting sanitation, and in helping to enforce these laws wherever it can, the Mansion House Council is doing good work and we are in full sympathy with its request for funds. The law, while far from perfect, is still capable of effecting much if vigorously and consistently carried out. Its inefficiency usually arises from one of two causes, the inactivity or the ignorance of those governed by it, and this inactivity or ignorance the Mansion House Council claims to stimulate or to instruct.

◆

The Anti-Vivisection Question.

THE columns of the *Times* for the past three weeks have contained letters dealing with the alleged abuse by physiologists of the position conferred upon them by the laws of their country in the matter of experiment upon the lower animals. Letters have also been published in reply to these, alleging, and in certain details proving, that the secretaries of the anti-vivisection societies have disseminated misleading literature to the public and have generally not conducted their opposition to the work of practical physiology in a candid manner. The correspondence in the *Times* has not yet come to an end and in our opinion our contemporary is doing thoroughly good service to the public by allowing the whole question of anti-vivisection to be thoroughly threshed out. It was probably with deliberate intention to clear the air by provoking a storm that some of the more contentious effusions have been published. In themselves several of them are ridiculous, but as contributions to a controversy they play their part, showing the mental attitude of the writers and giving the public a chance of gauging the general wisdom of their party. Nothing but good to the cause of humanity, as well as to the cause of science, should come from the publication of these letters; for the public, if it has read them and is reading them carefully, cannot fail to see on which side right lies, and cannot fail to detect which is the genuinely charitable man, which is the self-important propagandist, and which is the blubbering sentimentalist.

We are asked now and again by our readers what course they should pursue when an emissary of one of the anti-vivisection societies proposes to take the floor at the local town hall and to show up the loathsome cruelty of the medical profession. Our usual reply is to counsel inaction. Our motive in so doing has not been simply barbarous, although we are aware that to disregard the "arguments" of the platform anti-vivisectionist is to hurt him in his tenderest spot. Our motive has been rather to spare members of our profession needless trouble. Physiology is not a subject that can be made intelligible to the public at any time, while the cause of truth can never be served by arguing about the due relation of physiology to therapeutics with a man who has received no scientific or medical training. And on point of the objectors to these methods is that the profit is not derived from the sale of a natural surplus but is calculated upon for the raising of funds for the conduct of the department. Many prominent medical men are of the opinion that while it is not only proper but imperative that there should be a rigid inspection of all therapeutic serums made by private manufacturers or by boards of health it is unjust and contrary to the principles of political science that boards of health should be allowed to trade in such products. The mayor said that after May 1st he would have an inquiry instituted into the whole subject.

Public Baths for New York.

The United States are far behind European countries as regards public-bathing arrangements in the cities. New York itself—although some progress has been made in providing its poorer districts with bathing facilities—is still lamentably deficient in this respect It is said that Liverpool, with a population of 668,000 persons, has spent on public baths more than all American cities combined, while Glasgow almost equals Liverpool in the number of its public baths. Germany in particular and the continent in general are little behind England and Tokio, in Japan, with a population of slightly over 1,000,000, has 800 public baths. There is probably no civilised city in the world with a greater need of a bountiful water-supply for washing and bathing purposes than New York The supply of water to the private houses is amply sufficient but in the tenement district the dwellings are so overcrowded that bathing and all ablutionary observances must be conducted on the most primitive and restricted scale conceivable and in many cases it is a matter of impossibility for the entire family to get a thoroughly good wash. Dr. Simon Baruch has long identified himself with the movement for a public bath system for New York commensurate with its size and wealth—indeed, he may be called the pioneer of the public bath crusade. Dr. Baruch is an ardent advocate of shower-baths, holding that in every respect they are superior to tub-baths. Viewed from every standpoint public baths may be said to be an advantage, almost a necessity, to a large city. The municipality of New York has recently appropriated $300,000 (£60,000) for the further extension of the bath system, but, as a matter of fact, this sum will be but a drop in the ocean—$3,000,000 (£600,000) would not have been an excessive amount. Nevertheless, this grant may be regarded as an earnest of a more generous one in the future and in this light it should be thankfully received.

Paying Patients in New York City Consumption Hospital.

On Feb. 1st a building on Blackwell's Island in New York Harbour was handed over by the municipal authorities of the city for the treatment of poor persons suffering from pulmonary tuberculosis. Recently the New York Commissioner of Charities published a statement of the results attained so far at the institution. Since Feb 1st, 273 patients have been admitted affected with phthisis in a more or less advanced stage. Rather more than 50 per cent. of this number were in a very bad condition, many of them being beyond hope of recovery. The remaining 50 per cent. were of two classes—those who presented all the typical symptoms of the disease but were able to live in the ordinary way and those who, while afflicted with phthisis in a bad form, yet retained sufficient vitality to be up for the greater part of the day. Of the 273 patients admitted 55 have been discharged—50 as improved and five as showing no signs of improvement, 28 cases have been transferred elsewhere for operations or as exhibiting no symptoms of tuberculosis, 76 patients who were admitted in an advanced stage have died, and 114 remain in the hospital. Of those remaining 20 are new cases not yet classified, 40 are unable to leave their beds, and 54 are in the early stage. Of these latter 25 have shown marked improvement and have gained in weight an average of 6·75 pounds, 13 have improved more slowly but show an average increase in weight of 1·9 pounds, and 16 have not improved but show an average loss in weight of 1·31 pounds. On the whole the experiment has been a success and it will lead to a further extension of the system of thus treating needy consumptives.

April 25th

ALLEGED CRUELTY TO FROGS.—At Clerkenwell Police-court on May 3rd an officer of the Royal Society for the Prevention of Cruelty to Animals was granted a summons for alleged cruelty to frogs. The ground of complaint was that more than 100 frogs were kept in a glass fishbowl in a window of a shop where reptiles were sold and that some of them were dead and others were in a dying condition. They were intended to be used for feeding snakes.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the first examination of the Board at the April quarterly meeting of the examiners in the subjects indicated:—

Chemistry.—Charles James Aveling, University College Hospital; Bernard Richardson Billings, London Hospital; John Errol Moritz Boyd, St. Mary's Hospital; Lawrence Drew Ching, St. Bartholomew's Hospital; John Clarke, Firth College, Sheffield; Bevil Molesworth Collard, London Hospital; David Ernest Stephen Davies, St. Bartholomew's and King's College Hospitals; Francis Carminow Doble, King's College Hospital, John McDougall Eckstein, St Bartholomew's Hospital; Howard Robinson Elliott, Firth College, Sheffield; Sydney Frank Henderson Everill, Mason College, Birmingham; John Rowland Foster, University College Hospital; Joseph Tylor Fox, City of London School; Edward Armitage Gough, Yorkshire College, Leeds; William Robert Greening, Guy's Hospital; Walter Bristow Griffin and Rupert Lawrence Haines, St. Bartholomew's Hospital, Henry Edwards Griffiths, University College, Cardiff, Herbert John Hills, Guy's Hospital; Hugh George Hobson, Middlesex Hospital; Thomas Huddleston, Mason College, Birmingham, and Birkbeck Institute; Arthur Rocyn Jones, University College, Cardiff; John Iles Francis Knight and Harold William Latham, London Hospital; Frederick Evelyn Woolner Meadows and Gordon Nevil Montgomery, Middlesex Hospital, Gerald Hamilton Morris, Guy's Hospital; Frederick William Murray, University College, Liverpool; George Kelsey Breward Neal, Charing Cross Hospital; Malcolmson Knox Nelson, Queen's College, Belfast; Ernest Nuttall, Owens College, Manchester; George Singleton Parkinson, University College, Bristol; Percy Giles Vivian Pedrick, Guy's Hospital, Leonard Russell, King's College Hospital; Gerald Noel Lloyd Sebastian, St. George's Hospital; William Preston Skinner, Firth College, Sheffield; Sidney Slade, Middlesex Hospital; Thomas Lionel Smith, Yorkshire College, Leeds; Herbert McLean Staley, Owens College, Manchester, and Manchester Technical School; George Stone, London Hospital, Arthur Westray Swinburne, Yorkshire College, Leeds; Tom Timothy, University College, Cardiff; Sydney Vosper, St. Bartholomew's Hospital; Harry Wales, Yorkshire College, Leeds, Frederic Winn Walker, Owens College, Manchester; Charles Weller, Birkbeck Institute, and John Dill Williams, Queen's College, Belfast

Practical Pharmacy.—Arthur Joseph Ambrose, Westminster Hospital; Sydney Charles Gordon Amoore, Charing Cross Hospital, Urban Morris Asphen, Cambridge University and King's College Hospital; Kenelm Digby Bell, St. Bartholomew's Hospital; James Landells Blackie, Otago University and Middlesex Hospital; Gerald Arthur Bradshaw, St. Mary's Hospital John Butterworth, Owens College, Manchester; Percy Claude Vincent Bent, Sidney Clement Bowle, William Henry Bush, and John Brightman Copland, Guy's Hospital; Mortimer John Cromie, Westminster Hospital; Edgar Severn Ellis, St. Bartholomew's Hospital; Harry Loft Evans, St. Thomas's Hospital, Walter Taylor Finlayson, St. Mary's Hospital Hugh Bernard German and George Francis Hardy, Guy's Hospital; John Winn Ford Gillies, St Thomas's Hospital; Frederic Rosenberg Harris, St Mary's Hospital; Willoughby Henwood Harvey, St. Bartholomew's Hospital; Daniel Morgan Humby, Middlesex Hospital; Frederick Douglas Selmes Jackson and Frederick Charles Rienzi Mallins Knight, Guy's Hospital, William Wilfrid King and Robert Lecky, University College, Bristol, William Lovell and William Thomas McCowen, St. Mary's Hospital; Horace Palmer Margetts, St Bartholomew's Hospital; Anthony Mavrogordato, Oxford University and St. Thomas's Hospital; Herbert Edward Morris, Guy's Hospital, Jonas Morris, St Bartholomew's Hospital; Reginald Moyle, Durham University and Guy's Hospital; John Patten Nuttall, London Hospital; Felix Rawsthorne, Owens College, Manchester; Harold Round, Mason College, Birmingham; John Douglas Staley, Owens College, Manchester; Alfred Cuthbert Story, University College, Cardiff, and St. Mary's Hospital; Martin Bramley Taylor Guy's Hospital, James Tuttle, London; and Richard Hugh Williams, University College, Liverpool, and Owens College, Manchester

Elementary Biology.—Charles Edgar Harvey Adam, St. Bartholomew's Hospital, Charles James Aveling and Richard Barragry. University College Hospital; Winfred Kelsey Braman, Charing Cross Hospital; William Harvey Bennett, Owens College. Manchester; Bernard Richardson Billings, London Hospital, William Augustine Joseph Mingaye Briggs, St Thomas's Hospital; Charles Henry Renwick Bryan, Guy's Hospital; Martin Binns Studer Button, London Hospital; Charles Cecil St. Mary's Hospital; William Winsland Douglas Chilcot, Charing Cross Hospital, John Clarke, Firth College, Sheffield; Horace Godden Cole, St. Thomas's Hospital; Edmund Victor Connellan and Percival Sandy Connellan University College, Bristol, Cecil Frederick Curtis, Owens College, Manchester; Gustavus William Musgrave Custance, St. Thomas's Hospital; Archibald Davidson, Guy's Hospital; Richard Molesworth Denys and John McDougall Eckstein, St. Bartholomew's Hospital, Howard Robinson Elliott, Firth College, Sheffield, John Jackson Whatley Evans, Westminster Hospital; Leonard Edwards, London Hospital; John Herbert Fitzgerald, Charing Cross Hospital, Alexander Fleming, St. Mary's Hospital, Joseph Tylor Fox, City of London College, Frederick Holcombe Fuller, Municipal School of Science and Technology, Brighton; Eric Worsley Gandy, Cambridge University and Westminster Hospital; Edward Slade Goss, University College, Bristol Edward Armitage Gough Yorkshire College, Leeds, Cyril Douglas Graham, London Hospital; Henry Granger, St. Thomas's Hospital; Vivian Bartley Green-Armytage, University College, Bristol; Maurice Green, University College, Liverpool; Harry Martin Grey, Walter Bristow Griffin, John Herbert Gurley, and Rupert Lawrence Haines, St. Bartholomew's Hospital; Thomas

Huddleston, Mason College, Birmingham; Godfrey Martin Huggins, St. Thomas's Hospital; John Gladstone Ivers, Owens College, Manchester; Theodore Arthur Izard, St. Bartholomew's Hospital; Courtnay Cooper Keates, St. Mary's Hospital; William Robert Kilgour, St. Bartholomew's Hospital; William Herbert King, University College Hospital; James Johnson Louwrens, St. Mary's Hospital; Harold William Latham and Owen Reginald McEwen, London Hospital; Richard Hugh McGillicuddy, University College Hospital; Frederick Evelyn Woolner Meadows and Gordon Nevill Montgomery, Middlesex Hospital; Joseph Leopold Meynell, London Hospital; Richard Ash Moxon, St. Mary's Hospital; Frederick William Murray, University College, Liverpool; Henry Williams Nicholls, Middlesex Hospital; Roger Brighouse Nicholson, Owens College, Manchester; Philip Spencer O'Bryen-Taylor, St. Mary's Hospital; Charles Melton Ockwell, Guy's Hospital; Francis Budge O'Dowd, Mason College, Birmingham, Francis William O'Connor, Richard Dominic O'Connor, Max Onslow-Ford, and Frank George Page, St. Bartholomew's Hospital; Hubert Arnold Pallant, Guy's Hospital; George Singleton Parkinson, University College, Bristol; Frederic Eustace Leigh Phillips, London Hospital; Lionel Lewis Phillips, St. Bartholomew's Hospital; Cuthbert Grant Plumley, University College and Merchant Venturers' College, Bristol; Edward Campbell Pope, St. Mary's Hospital; George Andrew Russell, Mason College, Birmingham; Edgar Arthur Shirvell, London Hospital; Leslie Ernest Maule Smith, Charing Cross Hospital; Walter Heaton Smith, Owens College, Manchester; Francis Edgar Sprawson, Birkbeck Institution; George Stone, London Hospital; Arthur Arbuthnot Straton, St. Mary's Hospital; William Francis Sutcliffe, St. Thomas's Hospital; Edmund James Fairfield Thomas, University College, Bristol; St. John Alexander Molesworth Tolhurst, Guy's Hospital· Herbert Edmund Blaker Turner, Guy's Hospital; Walter George Howard Masterman Verdon, University College, Cambridge; Harold FitzVellacott and Louis Michael Waldron, London Hospital; Harry Wales, Yorkshire College, Leeds; and Harrie Bruce Wickham, University College, Liverpool.

UNIVERSITY OF CAMBRIDGE. — At the third examination for medical and surgical degrees, Easter term, the following candidates were successful:—

Part I. Surgery and Midwifery.—H. W. Atkinson, M.A., Caius; E. A. A. Beck, M.A., Clare; W. V. Braddon, B.A., Trinity Hall; W. H. Brailey, B.A., Queen's; W. F. Buckle, B.A., Caius; H. N. Burroughs, B.A., Trinity; R. Butterworth, B.A., Christ's; J. G. Cooper, Trinity; H. A. Cutler, B.A., Clare; H. H. Dale, B.A., Trinity; J. F. H. Dally, B.A., St. John's; R. S. Drew, B.A., Pembroke, G. G. Ellett, B.A., Catherine; D. A. Ellis, B.A., Downing; W. H. Fisher, B.A., Emmanuel; J. E. Frere, B.A., Pembroke; J. D. H. Freshwater, M.A., and H. U. Gould, B.A., Trinity; C. H. Gregory, B.A., Emmanuel; T. Guthrie, B.A., King's; C. F. Hardie, B.A., Queen's; W. L. Harnett, B.A., St. John's; E. T. Harris, B.A., Christ's; D. Holroyde, B.A., Trinity; W. W. Holtzmann, B.A., Christ's; C. R. Howard, B.A., Pembroke; B. Hudson, B.A., Clare; K. H. A. Kellie, B.A., Caius; F. S. Kidd, B.A., Trinity; P. W. Leathart, B.A., Clare; H. D. Ledward, B.A., Trinity, T. W. Mercer, B.A., Clare; G. R. Rickett, B.A., King's, T. St. Clair Smith, B.A., Trinity Hall; J. E. Spicer, B.A., Trinity; H. Statham, B.A., Christ's; J. M. Stenhouse, B.A., Sidney Sussex, W. M. Strong, M.A., Trinity; W. B. Swete-Evans, B.A., Clare; H. T. Thompson, B.A., and J. M. Twentyman, B.A., Christ's, H. Wales, B.A., Sidney Sussex; F. Whitaker, B.A., Trinity; J. H. F. Wilgress, B.A., H. Selwyn; C. R. Worthington, B.A., Caius; and G. A. Wright, B.A., Christ's.

Part II. Medicine.—J. F. Alexander, B.A., Trinity; J. A. Andrews, B.A., St. John's; G. F. Barham, B.A., Caius; B. L. T. Barnett, M.A., St. John's, J. Barnicot, B.A., Pembroke; J. M. Bennion, B.A., St. John's; L. Bousfield, B.A., Pembroke; A. S. Bradley, B.A., Caius; H. C. Brown, B.A., Emmanuel; H. S. D. Browne, B.A., and C. V. Bulstrode, B.A., Trinity; H. O. Butler, B.A., Emmanuel; F. R. Carroll, B.A., and H. H. Clarke, B.A., Trinity; G. L. Crimp, B.A., Caius; A. F. Elliott, B.A., Emmanuel; R. L. V. Foster, M.A., and G. D. Franklin, B.A., King's; E. H. Harrisson, B.A., Clare; G. P. D. Hawker, B.A., Caius; J. P. Hedley, B.A., and H. T. Hodgkin, B.A., King's; W. W. Jeudwine, B.A., H. Selwyn; E. H. Kitchin, B.A., Downing; A. P. Laycock, B.A., St. John's; G. E. Loveday, B.A., Caius; J. McBryde, B.A., King's; J. C. Matthews, B.A., Downing, F. D. Nicholson, B.A., King's; C. de C. Pellier, M.A., Clare, B. B. Sapwell, B.A., Corpus Christi; C. H. Sedgwick, B.A., Sidney Sussex, F. E. Shipway, M.A., Christ's; H. J. Shone, B.A., Emmanuel; J. E. B. Snell, B.A., B. Spearman, B.A., R. Spearman, B.A., and H. H. Stiff, B.A., Caius; G. E. St. C. Stockwell, B.A., King's, B. L. Thurlow, B.A., Caius; G. H. L. Whale, B.A., Jesus, and G. R. Wilson, B.A., and W. W. Wingate Saul, M.A., Trinity.

Pharmacology and General Pathology only.—C. Akerman, B.A., Caius; W. Hastings, B.A., Christ's; G. G. Hirst, B.A., Caius; C. W. P. Moffatt, B.A., Clare; R. N. Poignand, B.A., Caius; R. E. Whiting, B.A., King's; and R. G. Wills, B.A., St. John's.

The following candidates have satisfied the examiners in both parts of the examination in Sanitary Science and are entitled to the Diploma in Public Health:—

George Hugh Spencer Blackburne, John Augustus Herman Brincker, M.B., B.C. (St. John's), Isaac Alexander Davidson, Mohomed Abdul Ghany, Henry Albert John Gidney, Robert Walker Gray, George Haddow, John Russell Higson, Joseph Hunter, Alice Neville Vowe, Percy Wheeler Kent, Stanley Thorpe Lewis, M.B., B.C. (St. John's), William Joseph Lindsay, M.B., B.C. (Sidney Sussex), John MacDonald McCarthy, M.B., B.C. (Non-Collegiate), Thomas Joseph McDonogh, Arthur William James MacFadden, Richard Galway Murray, Burton Alexander Nicol, Eugene John O'Meara, Devi Datt Pandya, Richard Frank Rand, James Hood Rankin, Frederick Sanger (St. John's), Witney Charles Palmer Smith (Downing), George Sowden, James Russell Watson, and Willoughby Mason Willoughby, M.B., B.C. (Gonville and Caius).

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the President, Vice-President, and Council, held on May 6th, the following examiners were elected:—In anatomy: Ambrose Birmingham and Alexander Fraser. In physiology and histology: E. L'E. Ledwich and C. Coppinger. In ophthalmology: Arthur H. Benson and P. W. Maxwell. In pathology and bacteriology: Arthur Hamilton White. In pathology: Robert Allen. In midwifery and gynæcology; Frederick W. Kidd. In biology: John J. Burgess. In sanitary law and vital statistics: H. Benson Goulding. In engineering and architecture: J. Charles Wilmot. In dental surgery and pathology: Daniel Corbett, jun., and W. G. Story. In mechanical dentistry: George M. P. Murray and William Booth Pearsall. In chemistry and physics: Edward Lapper and R. J. Montgomery. In languages: L. J. Woodroffe. In mathematics, physics, dictation, and English essay: J. W. Tristram.

ROYAL INSTITUTION.—The annual meeting of the members of the Royal Institution was held on May 1st, Sir James Crichton-Browne being in the chair. The annual report of the Committee of Visitors for the year 1901, testifying to the continued prosperity and efficient management of the institution, was read and adopted, and the report of the Davy-Faraday Research Laboratory of the Royal Institution which accompanied it was also read. 44 new members were elected in 1901. 63 lectures and 17 evening discourses were delivered in 1901. The books and pamphlets presented in 1901 amounted to about 253 volumes, making, with 722 volumes (including periodicals bound) purchased by the managers, a total of 975 volumes added to the library in the year. Thanks were voted to the President, the treasurer, and the honorary secretary, to the committees of managers and visitors, and to the professors for their valuable services to the institution during the past year. The following gentlemen were unanimously elected as officers for the ensuing year:—President, the Duke of Northumberland; treasurer, Sir James Crichton-Browne; secretary, Sir William Crookes; managers—the Right Hon. Lord Alverstone, Sir James Blyth, Bart., Sir Frederick Bramwell, Bart., Dr. Thomas Buzzard, Dr. Donald Hood, Sir Francis Laking, Mr. George Matthey, Dr. Ludwig Mond, Dr. Hugo Muller, Mr. Edward Pollock, Sir Owen Roberts, Sir Felix Semon, the Right Hon. Sir James Stirling, Mr. John I. Thornycroft, and Mr. James Wimshurst; visitors—Dr. Henry E. Armstrong, Dr. Charles Edward Beevor, Mr. John B. Broun-Morison, Mr. Francis Elgar, Mr. Francis Gaskell, Dr. J. Dundas Grant, Lord Greenock, Mr. Maures Horner, Sir Henry Irving, Mr. Wilson Noble, Mr. W. R. Pidgeon, Mr. Arthur Rigg, Mr. W. S. Squire, Mr. Harrold Swithinbank, and Mr. Charles Wightman.—The Constitution of Crystals was the subject of the Friday evening discourse delivered at the Royal Institution on May 2nd by Mr. A. E. Tutton, who has been making researches which lead to the result that in any series of crystalline salts the properties of the crystals are functions of the atomic weights of the metals composing them. Models of the crystals of the sulphates of potassium, rubidium, and cæsium were shown, and it was pointed out that the mutual inclinations of the faces of the three salts changed progressively, following the numerical order of the atomic weights. It was also shown that in the changing values of the angles at which their optic axes were inclined crystals followed the order of the atomic weights of their metals. Numerous polarisation experiments were performed in illustration of the subject.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, MAY 1ST.

West African Medical Staff.

MR. CAINE asked the Secretary of State for the Colonies if Indian medical men bearing British degrees in medicine were eligible for appointments on the West African medical staff.—MR. CHAMBERLAIN replied: Indian medical men are not eligible for employment on the West African medical staff.—MR. CAINE: Why exclude them?—MR. CHAMBERLAIN: That is a matter for argument. There are circumstances which render the employment of medical men of Indian birth in West Africa undesirable.—MR. CAINE: I will raise the question on the vote for the salary of the Secretary of State.—MR. CHAMBERLAIN: By all means.

London Water Charges.

Mr. Kimber asked the President of the Local Government Board whether he would propose the insertion in the Water Bill of clauses to readjust the existing water-rates and to charge them on uniform principles through London, and so that the charge for water should be such as to prevent any deficiency in the water fund which might be a burden upon the rates; also provisions for securing uniformity of valuation for assessment, similar to those contained in the Valuation Metropolis Act, 1869, applicable to the district outside the county of London affected by the Bill; and whether he would propose provisions for the supply of water by meter compulsorily if required by consumers.—Mr. Grant Lawson, replying for Mr. Long, said: Such matters as the readjustment of water-rates or the supply by meter must, I think, be left to the consideration of the Water Board. A proposal will, however, be made before the joint committee to insert a provision in the Bill to the effect that the Water Board shall not, until otherwise authorised by Parliament, reduce the rates charged for the supply of water below those in force during the present quarter. An amendment of the law so as to secure uniformity of valuation for assessment will be one of the main objects of the proposed Government Valuation Bill. It would be outside the scope of the Water Bill.

MONDAY, MAY 5TH.

Water in Butter.

Sir Edward Strachey asked the President of the Board of Agriculture whether he was aware that by a recent decision of the High Court butter might be sold to the public which had been adulterated with a large percentage of moisture without infringement of the Margarine Act; and whether he would introduce a Bill to put a stop to the sale of an article which was prejudicial in the interests of the dairy industry of Great Britain and of the retailers and consumers throughout the country.—Mr. Hanbury replied: I am aware of the prejudice done to the makers of genuine butter both in this country and the colonies by the sale as milk blended butter of an article artificially loaded with 25 per cent. of water. The recent introduction of an authorised standard of butter will, it is to be hoped, if standards in such cases are to be of any real value, have the effect of preventing such an article being so sold, but should that not prove to be the case, further steps ought, I think, to be taken without delay to remedy the injustice done to both British and colonial farmers.

The Army Medical Service.

Captain Norton asked the Secretary of State for War if he would consider the advisability of granting to officers who had retired from the Army Medical Department and other branches of the service and were not liable to recall, but accepted service in the late national emergency, similar conditions with reference to pension and rank as were granted to reserve officers who had been re-employed.—Lord Stanley, for Mr. Brodrick, replied: Medical officers not liable to recall who volunteered to take the places normally occupied by medical officers of the regular army obtain similar conditions to reserve officers.

Physical Training for School Children.

Mr. Priestley asked the First Lord of the Treasury if His Majesty's Government would consider the appointment of a Royal Commission for England and Wales, similar to the one recently appointed for Scotland, to inquire into the question of the physical training of children in all public elementary schools.—Mr. Balfour replied: I have not yet had any opportunity of consulting the authorities of the Education Department, but as at present advised it seems to me as if it would be wise in the first place to await the results of the commission now inquiring into this very question in Scotland—an inquiry which, if not absolutely conclusive as regards England, must certainly throw an amount of light on the English question; and in the second place, to await the result of the discussion on the Education Bill now before the House.

TUESDAY, MAY 6TH.

Enteric Fever among the Troops in South Africa.

Sir Walter Foster asked the Secretary of State for War whether he could state the number of cases of enteric fever and the number of deaths from that disease which had occurred among the troops in South Africa in December, 1901, and in January and February, 1902; whether he was able to give any particulars as to the incidence of the disease upon camps and moving columns respectively; and whether any special precautions were being taken to prevent the occurrence of the disease in the columns and in the camps.—Mr. Brodrick replied: The figures for the three months are: December admissions 1507, deaths 224; January admissions 2760, deaths 396; and February admissions 2122, deaths 333. The principal medical officer reports that the enteric cases mostly come from the columns but it is not possible to obtain figures from the statistics to show this clearly. In the camps and stationary garrisons steps have been taken to have the water boiled and special officers selected to deal with the sanitary work of districts and the outbreak of disease. For mobile columns a scheme of providing safe water to fill the soldiers' water-bottles at all times has been prepared, involving an increase in the water-carts, and measures are being taken to carry this out. Officers have been specially instructed as regards the necessity of preventing the men from drinking water from unsafe sources but it is not too much to say that no instructions will prevent thirsty men committing such indiscretion and many soldiers when in hospital have admitted that they preferred the risk to the otherwise unavoidable delay.

Accidents with Petroleum Lamps.

Sir Mancherjee Bhownaggree asked the Home Secretary if he had seen the report of the coroner's inquest held on the bodies of seven young persons and children who perished in the fire at Hackney-road on April 19th last; if he had noticed the evidence given at the inquest by the inspector appointed under the Petroleum Act that the catastrophe, which was caused by the tilting of a lamp, occurred owing to the flash-point of the oil which escaped being as low as 88 degrees; if his attention had been drawn to the inspector's statement that such oil was largely sold in the East End, and that it was the cause of 26 fatal accidents last year; and whether he contemplated taking any steps to prevent the sale of petroleum the flash point of which was dangerously low.—Mr. Ritchie replied: Yes, sir, and I have caused the report of the case to be very carefully considered. From the evidence it would appear that the accident was caused by the fall of a lamp and the escape of the oil, both the lamp and oil being in a highly-heated condition. I am advised that in these circumstances a conflagration is likely to occur with any form of petroleum and in ordinary lamps. I do not find that the inspector stated that the oil used in this instance was the cause of the 26 fatal accidents last year. As a matter of fact in 12 of those cases the flash point of the oil was not known and in two cases it was over 100 degrees Fahrenheit. As regards the present case it is impossible to ascertain the exact cause of the heating of the lamp, but if this was in any way due to the oil it can only have been on account of its sluggish or slow-burning nature, and these qualities, I am advised, go rather with a high-flash than with a low-flash oil.

WEDNESDAY, MAY 7TH.

Accidents with Petroleum Lamps.

Mr. Leamy asked the Home Secretary whether, in view of the increasing number of fatal accidents arising from the use for domestic purposes of low flash oil, the Government intended to bring in a Bill to prohibit or regulate its sale, and if, until there was legislation on the subject, the Home Department would take steps to warn dealers in oil and the public generally of the danger in the use of low-flash oil.—Mr. Ritchie replied: I would refer the hon. Member to the answer which I gave yesterday to a somewhat similar question. The considerations set out in that answer, as well as the statistics generally, throw doubt in my opinion on the suggestion in the question that there is an "increasing number of fatal accidents arising from the use of low-flash oil." I would merely add that a paper containing a series of suggestions for the care and use of petroleum lamps, a most important element in this matter, was prepared and issued in large numbers by the Home Office a few months ago.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

Ball, C. R. H., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant House Physician to the Metropolitan Hospital.

Berkeley, Comyns, M.B., B.C. Cantab., M.R.C.P. Lond., has been appointed Lecturer on Practical Midwifery at the Middlesex Hospital.

Boyd, F. T., M.D. Lond., has been re-appointed Medical Officer of Health to the Chipping Sodbury Rural District Council.

Borthwick, Thomas, M.D. Edin., has been appointed Honorary Bacteriologist to the Adelaide Hospital, South Australia.

Brown, H. Harold, M.D. Brux., Major I.M.S., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

Burton, H., L.R.C.P. Irel., M.R.C.S., has been re-appointed Medical Officer of Health for Marple Urban District Council.

Butler-Hogan, J. F., B.A. R.U.I., M.D. Brux., D.P.H. Camb., &c., has been appointed Medical Officer of Health to the Tottenham Urban District Council.

Cook, Percival Robert, M.B. Univ. N.Z., has been appointed Public Vaccinator for the District of Waipara, New Zealand.

Cray, William James, M.B. Univ. N.Z., has been appointed Public Vaccinator for the District of Brunner, New Zealand.

Danks, W. S., M.B. Lond., has been appointed Civil Medical Officer to the South African Field Force.

Denning, C. E., L.R.C.S., L.K.Q.C.P. Irel., has been appointed Certifying Surgeon under the Factory Act for the Epping District of Essex.

Elliot, J. P., L.R.C.P. & S. Edin., has been re-appointed Medical Officer of Health for Bellingham Rural District Council.

Frost, Constance Helen, M.B. N.Z., has been appointed Assistant Bacteriologist to the Adelaide Hospital, South Australia.

Gough, William, M.B., B.S., B.Sc., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to the Hospital for Children and Women, Leeds.

Griffin, Lewis, M.R.C.S., has been re-appointed Medical Officer of Health of the Borough of Banbury.

Hicks, Charles, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory Act for the Horsmonden District of Kent.

Ivens, Frances, M.B. Lond., late Clinical and Assistant Pathologist, has been appointed House Surgeon to the Royal Free Hospital, Gray's-inn-road.

Jonas, Herbert Charlton, M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed an Honorary Medical Officer to the Barnstaple and North Devon Infirmary.

Liney, Lydia Ann, M.D. Brux., has been appointed Oculist in the Medical Department of the School Board for London.

Little, Andrew, M.B., M.S. Aberd., has been appointed Honorary Surgeon to the Eye and Ear Hospital, Bradford.

Lloyd, W. F., M.B., B.C. Cantab., has been appointed Assistant Surgeon to the Windsor Royal Infirmary.

Low, C. W., M.B. Durh., D.P.H., has been re-appointed Medical Officer of Health for Stowmarket Urban District Council.

Lynch, Arthur Francis, M.B., B.S. Adel., has been appointed Honorary Pathologist to the Adelaide Hospital, South Australia.

Mackenzie, Murdoch, F.R.C.S. Edin., has been appointed Port Health Officer for the Port of Westport, New Zealand.

McDougall, Olive, M.B. Lond., has been appointed House Physician to the Royal Free Hospital, Gray's-inn road.

Mossop, A. G., L.R.C.P. Irel., M.R.C.S., has been re-appointed Medical Officer of Health to the Port Sanitary Authority of Newhaven.

Nixon, J. A., M.B., B.C. Cantab., has been appointed Surgeon to the s.s. *Johannesburg*.

Noke, F. H., M.B. Lond., has been appointed Assistant House Surgeon to the Metropolitan Hospital.

Ormerod, A. L., M.D. Oxon., D.P.H., has been appointed Medical Officer of Health of the City of Oxford.

Purnell, Richard, M.D. St. And., has been appointed Medical Officer of Health of the Borough of Wells.

Reynolds, Francis Mortimer, M.B., C.M. Edin., has been re-appointed Medical Officer of Health for the Ottery St. Mary (Devon) Urban District Council for three years.

Ritchie, Alexander B., M B., M S. Edin., has been appointed Medical Officer to the Manchester School Board.

Roberts, E. J., M.B. Univ. N.Z., has been appointed Port Health Officer for the Port of Nelson, New Zealand.

Sangster, John Irin, M.R C.S., has been appointed a Member of the Board of Advice for the School District of the Burra, South Australia.

Sodhi, Bābā M. Singh, M.B., Ch.B. Edin., has been appointed Senior Assistant Medical Officer to the Portsmouth Asylum, vice Mr. John J. Glasgow.

Stephens, Stanley, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Newton Abbot (Devon) Workhouse, vice James Culross, resigned.

Scott, W. H., L.R C P. & S. Edin., L F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory Act for the Caton District of Lancashire.

Whitaker, E. T., M.B., B.Sc. Edin., has been re-appointed Medical Officer of Health for Wem Urban District Council.

Williams, E. C., M R.C.S., L R.C.P. Lond., has been appointed Surgeon to the P. and O. s s. *Peninsular*.

Wood, M. D, M.D. Durh., has been appointed Second Assistant Medical Officer to the Hayward's Heath Asylum.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Birmingham and Midland Eye Hospital.—Resident Surgical Officer. Salary £100 per annum, with apartments, board, and attendance

Birmingham General Dispensary.—Resident Locums. Terms 4 guineas per week, with apartments.

Birmingham General Hospital.—Aural Surgeon and Laryngologist.

Bristol City Lunatic Asylum.—Medical Assistant, unmarried. Salary £140 per annum, increasing to £160, with apartments, board, and washing.

Cancer Hospital, Fulham-road, S.W.—Junior House Surgeon. Salary at rate of £70 per annum, with board and residence.

Central London Sick Asylums at Cleveland-street or Hendon.—Assistant Medical Officer. Salary £120 per annum, with board and residence at Hendon Asylum.

Chelsea Hospital for Women, Fulham road, S.W.—Registrar. Honorarium of 20 guineas per annum.

City Asylum, Birmingham.—Resident Clinical Assistant, with board, residence, and washing. Honorarium at rate of £50 a year.

City of London Hospital for Diseases of the Chest, Victoria-park, E.—Two House Physicians for six months, with board, washing, and residence provided, and salary at rate of £30 per annum.

Colombo, Ceylon, Municipality of.—Medical Officer of Health. Salary equivalent to £400, rising to £500, and conveyance allowance

Cornwall Royal Infirmary.—House Surgeon (unmarried). Salary £100, increasing, with board and apartments.

Durham County Asylum.—Junior Assistant Medical Officer. Salary £150, rising to £180 a year, with apartments, board, laundry, and attendance.

Eccles and Patricroft Hospital, Lancashire.—House Surgeon. Salary £70, with board, residence, and washing.

Glamorgan County Asylum, Bridgend.—Locum Tenens. Board and 4 guineas a week.

Gravesend Hospital.—House Surgeon. Salary £90 per annum, with board and residence.

Horton Infirmary, Banbury.—House Surgeon and Dispenser. Salary £80 per annum, with board and lodging.

Jerusalem British Ophthalmic Hospital.—Clinical Assistant. Salary £100 and allowances.

Kent and Canterbury Hospital.—Assistant House Surgeon, unmarried Salary £60 a year, with board and lodging

Kent County Asylum, Barming Heath, Maidstone.—Fourth Assistant Medical Officer and Pathologist, unmarried. Salary £175 per annum, rising to £200, with quarters, attendance, &c.

Kincardine, Ross-shire, Parish Council.—Resident Medical Officer. Salary £72 10*s.* as Medical Officer and £5 per annum as Vaccinator, with lunacy fees in addition.

Kings Norton and Northfield Urban District Council and Infectious Diseases Hospital.—Medical Officer of Health and Medical Superintendent. Combined salary £500 per annum.

Lancashire County Asylum, Whittingham.—Junior Assistant Medical Officer, unmarried. Initial salary £150, with apartments, board, washing, and attendance.

Liverpool Stanley Hospital.—Senior House Surgeon Salary £100 per annum, with board, residence and washing, also Third House Surgeon. Salary £70 per annum, with board, residence, and washing.

Metropolitan Asylums Board Asylum, Caterham, Surrey. Assistant Medical Officer, unmarried. Salary £150 per annum, rising to £170, with rations, lodging, attendance, and washing.

Metropolitan Asylums Board Fever and Small-Pox Hospitals.—Assistant Medical Officers, unmarried. Salary £180 per annum, rising to £240, with board, lodging, attendance and washing.

Miller Hospital and Royal Kent Dispensary, Greenwich road.—Dentist.

Monkwearmouth and Southwick Hospital, Sunderland.—House Surgeon. Salary £50 per annum, with board, lodging, and washing.

New Hospital for Women, 144, Euston-road, N.W.—Medical Woman to take charge of the Roentgen Ray Department. Also House Physician, House Surgeon, and Clinical Assistant (all female).

Northampton St. Andrew's Hospital for Mental Diseases.—Assistant Medical Officer for six or seven months. Salary four guineas a week, with board, lodging, and washing.

North-West London Hospital, Kentish Town-road.—Second Honorary Anæsthetist. Also Resident Medical Officer. Also Assistant Resident Medical Officer, both for six months. Salary at rate of £50 per annum each, with board, residence, and washing.

Nottingham General Dispensary.—Assistant Resident Surgeon, unmarried. Salary £160 per annum, with apartments, attendance, light, and fuel.

Oxford Radcliffe Infirmary.—House Surgeon, also Junior House Surgeon, both for six months. Salaries £40 and £30 respectively, with board and lodging.

Poplar and Stepney Sick Asylum District, Bromley, E.—Second Assistant Medical Officer. Salary £100 with rations, apartments, and washing.

Royal Albert Hospital, Devonport.—Resident Medical Officer. Salary £110 per annum, with board and lodgings.

Royal South Hants and Southampton Hospital, Southampton.—Senior and also Junior House Surgeon. Salaries £120 and £60 per annum respectively, with rooms, board, and washing. Also Dentist.

Royal Westminster Ophthalmic Hospital, King William-street, West Strand, W.C.—Clinical Assistants for six months.

Tottenham Hospital.—House Surgeon. Salary £50 per annum, with board, residence, and laundry.

Wallasey Dispensary and Victoria Central Hospital, Liscard.—House Surgeon, unmarried. Salary £100, with board, apartments, and service.

West Riding Asylum, Wakefield.—Pathologist and Assistant Medical Officer. Salary £140, rising to £160, with apartments, board, washing, and attendance.

Western General Dispensary, Marylebone-road, N.W.—Second House Surgeon, unmarried. Salary £80 a year, with board, residence, and laundry.

Wilts County Asylum, Devizes.—Assistant Medical Officer, unmarried. Salary £150 a year, rising to £180, with board, residence, attendance, and washing.

Wolverhampton and Staffordshire General Hospital.—House Physician, also House Surgeon. Salary (in each case) £100 per annum, with board, lodging, and washing.

The Secretary of State for the Home Department, Whitehall, S.W., gives notice that there is a vacancy for a Medical Referee under the Workmen's Compensation Act, 1897, for the Whitchurch, Crewe, and Nantwich County Courts in Circuit No. 9.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeon, under the Factory Acts, at Cruden in the county of Aberdeen, at Haltwhistle in the county of Northumberland, at Youlgreave in the county of Derby, and at Esher in the county of Surrey.

Births, Marriages, and Deaths.

BIRTHS.

Goddard.—On May 4th, at Norfolk-crescent, Hyde-park, W., the wife of W. H. Goddard, M D. Cantab., of a daughter.

Harvey.—On April 27th, at Hartfield-road, Wimbledon, the wife of Joseph Harvey, M.B. Univ. Irel., of a daughter.

Pearson.—On April 29th, at Alva street, Edinburgh, the wife of C. Mowbray Pearson, M.B., Ch B. Edin., of a daughter.

Turner.—On May 2nd, at Westbury, Purley, Surrey, the wife of S. Duke Turner, M.B, B S. Durh., of a daughter.

MARRIAGES.

Playfair—Winton.—On Wednesday, April 30th, at the parish church, Speldhurst, Kent, by the Rev. Charles Stuart Macdonald Playfair, M.A., parish church, Folkestone, cousin of the bridegroom, assisted by the Rev. D. D. Mackinnon, M.A., rector of Speldhurst, David Thompson Playfair, M D., Bromley, Kent, eldest son of the late Rev. David Playfair, B.A., Abercorn, N.B., to Annie Seaton (Birdie), only daughter of Edwin William Winton, Etherton-hill, Speldhurst, Kent.

Wagstaff—Beasley.—On April 29th, at St. Mary's Church, Dallington, Northampton, Frank Alexander Wagstaff, M.R.C S., L.R.C.P. Lond., to Margaret Elizabeth, youngest daughter of the Rev. T. C. Beasley, vicar of Dallington.

DEATHS.

Berry.—On May 2nd, at Pembridge-villas, W., Henry Thomas Berry, M R.C.S., in his 83rd year.

Bolton.—On April 23th, in South Africa, John Usherwood Bolton, M.R C.S., L R.C.P. Edin.

Stephens.—On April 30th, at Lynton, N. Devon, Daniel Robert Porritt Stephens, M.B. Camb., F.R.C.S. Eng

Turner.—On the 6th inst., at Hove, Theophilus Bryett Turner, M R.C S., second son of the late Rev. Thomas Turner, rector of Port Royal, Jamaica Aged 56 years.

Venn.—On May 6th, 1902, at 13, Vicarage Gate, Kensington, W., Emma, the beloved wife of Albert J. Venn, M.D., of 63, Grosvenor-street, Grosvenor-square, W., and late of Kemnal Wood, Chislehurst. Funeral service at St. Mary Abbots, Kensington, at 2 o'clock on Saturday, May 10th. Interment at Kensal Green Cemetery at 3 30. Friends will please accept this, the only, intimation.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE OBLIGATION (?) OF A MEDICAL MAN TO ATTEND.

ONCE again has the question whether a medical man is bound to attend a summons to a patient been brought up in a coroner's court. The case in question came before the coroner for the city of Canterbury at an inquest held on April 25th. The inquest was to inquire into the death of a woman named Twyman who had died in the union infirmary. From evidence given by the husband at the inquest it appeared that the woman was taken ill on a Sunday with a fit. Witness's sister-in-law went for a medical man who was unable to come. On the Monday Mr. Brian Rigden arrived and recommended that the patient should be removed to the infirmary. This was done. Mr Frank Wacher, the medical officer of the infirmary, deposed to seeing the patient twice on the night of her admission and upon several occasions next day. On Tuesday morning a child was born, but the woman died at 4 30 A.M. on the Wednesday. Death was due to puerperal convulsions. Mrs. Vaughan, who is Mrs. Twyman's sister, deposed to being sent by Mr. Twyman for a medical man. The first to whom she applied was Mr. Z. Prentice who recommended her to get Mr. Rigden. Mr. Prentice stated in court that he refused to go because he knew that he might be kept a long time and he was bound to appear early on the following morning in the Court of King's Bench. He recommended Mrs. Vaughan to get someone else but not particularly Mr. Rigden. Mrs. Vaughan, in the remainder of her evidence, stated that she had applied to Mr. Rigden who replied that he had company and could not come. He also advised her to go for someone else, but she replied that she should not. Mr. Rigden in his evidence described Mrs. Vaughan's visit. According to him she said that Mrs. Twyman had been ill for some time and was expecting to be confined in about a fortnight He recommended her to get someone else because he had a visitor who had just arrived from abroad. Next morning Mr Twyman arrived and asked him to attend. He went in the afternoon and arranged for the woman to be removed to the infirmary, as he found Mrs. Twyman suffering from the effects of a fit. Mr. Twyman had not been for anyone else in the night and he thanked Mr. Rigden for getting his wife into the infirmary. At this point a juryman named Belsey said to witness: "Had it been a person in good circumstances you would have gone It is a question of pounds, shillings, and pence." Mr. Belsey, in answer to the coroner, said that the public paid for doctors He considered that Mr. Rigden's evidence was not satisfactory. The coroner pointed out that no medical man was bound to go to a case unless he had been previously engaged to do so. Medical men were not public property. The jury returned a verdict in accordance with the medical evidence. We hope that the coroner's remarks will go home, but there is a class of persons the members of which often figure on juries who are firmly convinced that medical men are bound to attend any and every summons. For the information of Mr Belsey and those like him we say that no medical man is bound to go to any case, unless, as the coroner pointed out, he has previously engaged himself to do so. Mr. Belsey's energies are wasted at Canterbury; he should go to Clyne in Sutherlandshire, where they look upon a medical man as a sort of parish servant.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—I have a slight case of melancholia in a middle-aged married woman. On awaking in the morning she shouts continuously and digs her nails into and pinches her husband. She says that she cannot work, but about midday when the work is done she is able to eat her dinner and perhaps go out for a walk or play cards with her husband. He cannot put up with her any longer and would be willing to pay from 10*s.* to 15*s* a week to get her away for a bit in the hope that a change and discipline would do her good. I should be obliged if someone could assist me in this matter —I am, Sirs, yours faithfully,

FRED. W. BARTON, M R.C.S. Eng , L.R.C.P. Lond.

54, Stockwell Green, S.W.

FALSE COLOURS.

WE have received a copy of the *Malthusian* for May. On p. 40 appears a list of members of the Medical Branch of the Malthusian League and among those members we find the following entry:—"Dr. H. S. Schultess Young, M A M D , 16, Queen Anne's-gardens, Bedford Park, London, W." In February, 1897, our attention was drawn to a leaflet and a press ticket concerning a meeting organised by the National Anti-vaccination League. On both the leaflet and the ticket appeared the name of H. S Schultess Young, Esq., M A., M.D. In our issue of Feb 27th, 1897, p 641, we stated that the name of Mr. Schultess Young did not appear on the current Medical Register. Mr. Schultess Young thereupon wrote to us saying that our remark was perfectly unexceptionable He added: "But inasmuch as it might be hastily inferred that I have ever represented myself as an M.D. *tout court*, or by any inference upon the Medical Register, allow me to contradict that supposition with great emphasis. Nor do I know of any person who has even by inference so described me." Mr. Schultess Young informed us that he did not attend the meeting because he was in bed with an injured leg so that he had not appeared on a platform where he had been "billed" as M.D. Perhaps he will now take steps, if he is not M.D , to have himself correctly described in the *Malthusian*. We imagine he receives the paper monthly and that he must be aware that he is described as M.D. He has been connected with "Malthusianism" at least since 1891.

THE GRADUAL DEVELOPMENT OF FAHRENHEIT'S THERMOMETRIC SCALE.

IN THE LANCET of Feb. 22nd, p. 565, we quoted some passages from an article on Fahrenheit's thermometer which Sir Samuel Wilks had published in *Knowledge*, and in the May number of that journal there is a further contribution on the same subject by Professor Cleveland Abbe, of the United States Department of Agriculture, Washington, D.C. Professor Abbe doubts if Fahrenheit obtained any of his ideas from Sir Isaac Newton and he refers those desiring more information either to the first chapter of his own (Abbe's) Treatise on Meteorological Apparatus and Methods, Washington, 1887, or to an elaborate article by Renou in the *Annuaire* of the Meteorological Society of France. Professor Abbe says:—

> "There is every evidence that the Fahrenheit scale began with his use of plus 90 as the upper limit of the temperature of the human body, and minus 90 for the lowest temperature of the air in Europe, and also the temperature obtained by the mixture of salt and ice. Fahrenheit subsequently used a second scale in which plus 12 and minus 12 replaced the plus 90 and minus 90. In 1714 he adopted a third scale—viz , plus 24 for the temperature of the body and zero for the lowest temperature at Dantzic in 1709. His fourth scale was plus 96 for the temperature of the human body and zero for the great cold of 1709 This scale gave him 32 as the temperature of melting ice, but that natural point was not directly adopted by him. With this first satisfactory mercurial thermometer (made in 1721, and whose scale was graduated according to this last system but extended much farther upward, by extrapolation) he found that the boiling-point of water was constant, or nearly so, at 212 degrees. The fact that Newton's 'arithmetic scale' read 33 or 34 for boiling water had no influence with Fahrenheit in the formation of his scale."

TRAINED NURSES REGISTRATION SOCIETY.

To the Editors of THE LANCET.

SIRS,—As a medical practitioner of many years' experience it occurs to me that the time has now arrived to place trained nurses on a firmer footing affording them, as well as the general public, protection against impositions. To meet this difficulty I suggest that a registration society should be formed under Government supervision to be called "The Trained and Registered Nurses' Society," adopting a universal uniform or badge, with the power to impose a penalty or fine on anyone assuming the same unjustly. I shall feel very grateful for any hints or suggestions as to how to proceed in this important scheme which will render tangible service to the most noble and unselfish portion of our fellow creatures —I am, Sirs, yours faithfully,

HENRY BELCHER, M.D. Erlang. (retired).

28, Cromwell road, Hove, Brighton.

TRANSFUSION *VERSUS* SUBCUTANEOUS INJECTIONS.

To the Editors of THE LANCET.

SIRS,—May I ask some of your correspondents to enlighten me on the following matters (1) In saline transfusion is there not greater safety in the subcutaneous introduction of normal saline over the intravenous route where the operation of opening a vein entails, besides a more elaborate technique, the danger of thrombosis and embolism? (2) What are the etiology, prognosis, and treatment of membranous colitis?

I am, Sirs, yours faithfully,

St. Louis, Mo., April 22nd, 1902. J. ROSS CLEMENS, M.R C.S. Eng.

THE POWERS OF A VESTRY.

To the Editors of THE LANCET.

SIRS,—Will you kindly give me information on the following case in next issue of THE LANCET? It is proposed by the select vestry of the church here to add an additional piece of ground to the existing graveyard at the church This would bring the graveyard to a distance of less than 90 feet from the actual wall of a dwelling-house. Is this legal? Is there any legislation on the subject? The place is a portion of a rural district under the Local Government (Ireland) Act, 1898. The town is non municipal, population 1600 The sanitary authority is the district council. *Is it lawful for the vestry to make the ground or have they first to obtain formal permission, and from whom?*

I am, Sirs, yours faithfully,

R. D. C.

April 28th, 1902.

*** By the Local Government (Ireland) Act of 1898 there were transferred to the district councils constituted by that Act the duties of burial boards exercised before by the rural sanitary authority and in certain cases by boards of guardians, under the Public Health (Ireland) Act, 1878. By the same Act the whole of the business of the rural sanitary authority of each district was transferred to the district council. In the Public Health (Ireland) Act, 1878, now enforced by the district council in respect of burial grounds, our correspondent will find a large number of sections dealing with opening, closing, and otherwise regulating burial grounds. We observe that the 174th section forbids new ground to be appropriated as a burial-ground or as an addition to a burial ground nearer than 100 yards to any dwelling house without the consent of the owner, lessee, and occupier of such dwelling house. We also observe that the Local Government Board of Ireland is given considerable powers of interference where its disapproval is invoked in the case of the threatened opening of new burial grounds. We are not, however, sufficiently informed as to the precise circumstances in which the proposed new addition to a burial-ground referred to by our correspondent is to be made or as to the rights claimed by the select vestry to be able to advise him positively as to the position of the district council in the matter or as to that of private individuals. The district council, however, appears to us to be primarily the party which should interfere should interference be deemed necessary, and it seems to us probable that a communication made to its clerk would elicit information as to the attitude which it is prepared to adopt. We should suggest communication with the Local Government Board should there be any question of the district council omitting to perform a duty assigned to it.—ED. L.

PROPOSED MEMORIAL TO THE LATE SURGEON GENERAL W. NASH, A.M.S.

A REVOLVING SHELTER FOR PHTHISICAL AND OTHER CASES.

DR A. EYTON LLOYD of Rhyl writes, in reply to the question asked by "Sanitation" in THE LANCET of May 3rd "We have two of Boulton and Paul's (Norwich) revolving shelters at the Royal Alexandra Hospital. They are perfect if placed upon a dry—concrete preferable—foundation."

THE PREHISTORIC REMAINS RECENTLY ACQUIRED BY THE BRITISH MUSEUM

To the Editors of THE LANCET.

SIRS,—With reference to Mr. R Henslowe Wellington's letter in your issue of May 3rd, p. 1293, the following quotation may interest some of your many readers. In "The Realms of the Egyptian Dead" (Ancient East Series: David Nutt) Dr K. A Wiedemann, Professor of Egyptology in the University of Bonn, says (p 41): "The corpse was laid carefully in the coffin, the mouth closed, the arms crossed on the breast or laid straight alongside the body, which was usually stretched horizontally on the back. In earlier periods there are some exceptions to this rule. In the Nagada period, before that of the Pyramids, when embalming was far less common, the bodies were usually placed in a crooked position and so they have been found as skeletons, the knees drawn up to the breast, the arms resting partly upon them, and the hands placed over the face. The dead must rest in the grave in the position in which the child awaits its entrance into the world, which by further analogy was ascribed also to the soul awaiting the resurrection. Somewhat later, and down to about 2000 B C., the corpse was often placed upon the left side, or if on the back the head was turned to the left That was the direction—looking towards the west and the realm of the dead—in which it was believed that the dead man could see out of his coffin and step forth from it To express this possibility more vividly, on a corresponding spot outside the coffin were painted or carved in relief two great eyes out of which the dead man's eyes might look."

I am, Sirs, yours faithfully,
Upper Gloucester place, N W., May 5th, 1902. GEORGE PERNET.

THE R A M C. UNIFORM

To the Editors of THE LANCET.

SIRS,—As volunteer medical officers are now ordered to wear "Sam Browne" belts of the R A.M C pattern except in review order I shall esteem it a favour if you or any of your readers will acquaint me with the differences of this belt as compared with the combatant officers'. Being desirous of obtaining this new belt I sent up to two military outfitters and they both sent me belts *exactly* similar to that worn by the executive officers —I am, Sirs, yours faithfully,

May 6th, 1902. SURGEON CAPTAIN.

⁂ There is only one "Sam Browne" belt —ED L

FEES FOR INSURANCE EXAMINATIONS.

DR. EDGAR DU CANE has forwarded for our inspection two schedules relative to the medical examination of two candidates for insurance in the Yorkshire Insurance Company, 2, Clare-street, Bristol The covering letter from the secretary of the Company, Mr Goodchap, informs Dr. du Cane that "the proposals being under £100 the candidates will pay your fee" On looking at the schedules we estimate that to fill them up properly would entail for each one at least three quarters of an hour's work. We cannot see why the fact of the sum to be assured being under £100 should make the patient liable for the fee. It takes, or it should take, just as long to examine a patient who wishes to be insured for £100 as one who wishes to be insured for £10,000 The client of the medical man is the insurance society, and not the person wishing to be insured. We recommend Dr. du Cane to refuse the services asked of him.

THE "Y" FUND.

SURGEON-GENERAL H. S. MUIR begs to acknowledge, with thanks, donations towards the "Y" Fund from Mrs. J. de Pass, Mrs Pariente, Miss Clibborn, Mr. J. A. St G. Whitty, Mr. J. H. Morgan, Dr. G. Brown, Mr. W. H. Meredith, Deputy Surgeon General E. M Sinclair (retired), Lieutenant-Colonel W. Johnston, A.M.S. (retired), Lieutenant Colonel H. A. H. Charlton, A M S. (retired), Surgeon-Lieutenant-Colonel E. A. Roe (retired), Brigade-Surgeon S. K. Ray (retired), and the following officers of the Royal Army Medical Corps: Colonels J. Maturin and M. D. O Connell; Lieutenant-Colonels R. Blood, J. Martin, M. W. Kerin, R. W. Mapleton, and A. Asbury, Majors G. E. Moffet and G. F. Alexander, and Captain P. H. Whiston. The fund now amounts to £91. It may be explained that this is in response to an appeal made privately to members of the profession for benevolent aid in a distressing case which has been described in a letter sent to a limited number of medical men (who would help the cause by kindly "handing on" to *confrères*). Should any reader of THE LANCET desire further particulars with a view to expressing *practical sympathy*, a copy of the letter will be forwarded on application to Surgeon-General Muir, 26, Kensington-gardens terrace, Hyde Park, London, W.

THE MEDICAL PROFESSION AND THE PUBLIC VACCINATOR.

WE have received from a correspondent the following statement of the situation between himself and a brother medical man—the public vaccinator for the district—for it will not be difficult to see that it is B who addresses us.

> In a densely populated district there are two practitioners, A and B, B having only recently started. A was appointed to the post of public vaccinator when he was the only medical man in the district and the appointment has been recently confirmed by the Local Government Board. As in many other districts, certain patients have preferred having their children vaccinated privately and not by the public vaccinator. Last week some patients called upon B, requesting B to vaccinate their children B made an appointment with the patients to vaccinate their children in the course of two or three days. In the meantime A called and was at once informed that arrangements had been made with B. He then stated *that B was not allowed to vaccinate and further that if he (A) did not vaccinate the children he would "report them." Under this intimidation A vaccinated the children against their parents' consent.* What remedy has B against A in such circumstances? Can B sue A for damages for deliberately stating that he (B) is not allowed to vaccinate?

In commenting upon this story we have to remember that we have only B's side of the case before us and that B depends for his information as to A's words upon the parents of the vaccinated children. The parents state that A has alleged that B was "not allowed to vaccinate" and it is the parents, too, who declare that they have been intimidated B. can do nothing unless he is certain that the evidence of the parents is trustworthy and will be forthcoming. Having satisfied himself, or preferably his solicitor, upon these points, he might represent to A the necessity for an apology. We are not blind to the difficulties with which public vaccinators have to contend, but they place themselves wholly in the wrong if they attempt to secure a monopoly for themselves to the prejudice of their fellow-practitioners. B must consult his solicitor with regard to the questions with which he closes his statement.

AN OFFER.

To the Editors of THE LANCET.

SIRS,—I have a set of the *British and Foreign Medico-Chirurgical Review* which I shall be glad to give to any medical library that would like to have it.

I am, Sirs, yours faithfully,
L. M. GRIFFITHS.
11, Pembroke-road, Clifton, Bristol, May 6th, 1902.

◆

M B—Our correspondent has presumably consulted that portion of the calendar of his university which deals with the examination for the degree in question. From our point of view he has a right to the style of "Doctor."

During the week marked copies of the following newspapers have been received:—*Welsh Gazette, Surrey Advertiser, Morning Herald (Perth, N Z), Coventry Herald, Belfast News, Birmingham Daily Mail, Municipal Reformer, Yorkshire Mercury, Liverpool Daily Post, Herts Advertiser, Times of India, Reading Mercury, Mining Journal, Local Government Chronicle, Hertfordshire Mercury, Windsor and Eton Express, Daily Telegraph, St. James's Gazette, Pharmaceutical Journal, Manchester Guardian, Dublin Evening Telegraph, Gazette Médicale de Paris, City Press, Australasian Medical Gazette, Centralblatt für Allgemeine und Pathologische Anatomie, Bulletin de l'Académie de Médecine, &c.*

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

Communications, Letters, &c., have been received from—

A.—Mr. S. B. Atkinson, Lond.; Messrs. Arnold and Sons, Lond.; Dr. Altdorfer, Wiesbaden.

B.—T. B. Browne, Ltd., Lond.; Messrs. Benton and Stone, Birmingham; Bristol Corporation, Town Clerk of; Dr. J. H. R. Bond, Prescott, Ontario; Messrs. J. and H. Bell, Nottingham; Messrs. J. H. Booty and Son, Lond.; Mr. James Berry, Lond; Mr. Haydon Brown, Surbiton; Dr. D. Brown, Northampton; Mr. H. Norman Barnett, Knock; Mr. H. Beattie, Banbury; Dr. A. W. G. Bagshawe, Nimuli, East Africa; Birmingham City Asylum, Secretary of; *Brighton Herald*, Office; Mr. G. Brown, Redhill; Mr. G. N. Bellairs, Lond.; Sir T. Lauder Brunton, Lond.

C.—Mrs. Cowie, Lond; Messrs. Cockett and Henderson, Lond.; Mr. C. J. Croft, Lond.; C. R. G.; Dr. A. Carbonetti, Badia Calavena; Dr. A. Collie, Fočcy; *County Asylum, Whittingham*, Medical Superintendent of; Dr. S. Gurney Champion, Norwich; Mr. J. Ross Clemens, St. Louis; Dr. Harry Campbell, Lond.; Mr. Jackson Clarke, Lond.; Messrs. Cassell and Co, Lond.; Mr. G. M. Cathcart, Glasgow; Dr. J. Cantlie, Lond.

D.—Mr. W. Dowse, Nottingham; Dr. A. B. Dunne, Bootle; Messrs. C. Delacre and Co, Brussels; Digestive Food Co., Paisley, Messrs. Deverell, Sharpe, and Gibson, Lond.; Director-General, Army Medical Service; Mr. D. O. Davies, Llandrindod Wells; Mr. E. Darke, Lond.; Mr. Charles Davies, Lond.; Messrs. C. Dreyer and Co., Lond., Durnam County Asylum, Winterton, Clerk of.

E.—Messrs. Evans, Lescher, and Webb, Lond.; Dr. Elkind, Lond.; Mr. C. Edwards, Cheltenham; Miss Eames, Bournemouth.

F.—Mrs. Fawssett, Tooting.

G.—Dr. S A. Gill, Formby; Great Eastern Railway Co, Lond., Continental Traffic Manager of; Dr. W. H. Gilbert Baden Baden; Glamorgan County Asylum, Bridgend, Clerk of, Dr. A. E. Giles, Lond.

H.—Dr. Jobson Horne, Lond.; Mr. H F. St. Hill, Windlesham; Mrs. Hilliard, Alresford, Messrs. Haasenstein and Vogler, Geneva; Mr. H. E. Haynes, Bedford; Dr. H. E Hooper, Lond.; Dr. J. S. Hooker, Lond.

J.—Mr. T. Bowen Jones, Whitland; Mr. Robert Jones, Liverpool.

K.—King Edward's Hospital Fund for London; King's College Hospital, Resident Medical Officer of; Mr. B. Kuhn, Lond.; Kent and Canterbury Hospital, Secretary of; Dr. S. J. Kirby, Hoxne; Messrs. R. A. Knight and Co., Lond.

L.—Mr. A. Lindsay, Liscard; Liverpool Stanley Hospital, Secretary of; Captain J. C. Holdich Leicester, I.M S., Bombay; L. M. O.; *Local Government Board for Scotland*, Secretary of; Mr. H. Littlewood, Leeds; Dr. P. W. Latham, Cambridge; Miss C. M. Lowe, Potters Bar; London Life Association, Secretary of; Messrs. Lee and Martin, Birmingham; Mr. H. Littlewood, Leeds.

M.—Dr. J. A. Macdougall, Cannes; Mr. C. Midgley, Manchester; Maltova Food Co., Leeds; Messrs. E. MacGeorge and Co., Lond.; Monkwearmouth, &c., Hospital, Sunderland, Secretary of; Mr. *E. B. Meyrowitz, New York*; C. Midgley, Ltd., Manchester; Municipality of Colombo, Ceylon, Clerk of; Frau Mutter, Freiburg; Dr. E. W. Martin, Ogmore Valley; Mr. T. A. Marks, Lond.; Messrs. C. Mitchell and Co., Lond.; Mutual Life Insurance Co. of New York, Manager of; Medical Graduates' College and Polyclinic, Lond.

N.—Naval Medical Department, Director-General of; Mr. J. C. Needes, Lond.; Mr. H. Needes, Lond; Mr. G. P. Newbolt, Liverpool, Dr. D. Newman, Glasgow.

O.—Mr. R. Oldenbourg, Munich.

P.—Mr. Y. J. Pentland, Edinburgh; Dr. R. Derwent Parker, Kimberley; Dr. F. M. Pope, Leicester; Mr. B. H. Paul, Lond.; Messrs. Peacock and Hadley, Lond.

R.—Dr. C. A Rayne, Lancaster; Rochdale and District Medical Society, Hon Secretary of; Royal South Hants, &c., Hospital, Southampton, Secretary of; Royal Society, Assistant Secretary of; Mr. F. Reynolds, Leeds; Messrs. Reynell and Son, Lond.; Royal Southern Hospital, Liverpool, Secretary of; Dr. J. Ritchie, Oxford.

S.—Mr. H. W. Scriven, Lond.; Messrs. W. B. Saunders and Co., Lond.; Mr. F. W. Sears, Lond.; The Standard Wine Association, Lond.; Surgeon, Liverpool; Monsieur J. Sabatier, Paris, Sanitary Wood Wool Co, Lond.; Captain R. Selby, R.A.M.C., Standerton, South Africa; Mr. B. C. Stevens, Rotherham; Society for Suppression of Opium Trade, Secretaries of; Scholastic, Clerical, &c., Association, Lond.; Messrs. J. Smith and Co., Lond.; Smith's Advertising Agency, Lond.; Surrey County Council, Clerk of; Stolzenberg File Co., Manager of.

T.—Dr. H. S. Taylor, Ficksburg; Dr. H. Taylor, Lond.; T. J. C.; Mr. J. Turner, Devizes.

U.—University College, Lond., Treasurer of; University College Hospital, Secretary of.

W.—Dr. Essex Wynter, Lond.; Dr. Tucker Wise, Montreux; Dr F. R. Walters, Farnham; Messrs. W. Wood and Co., New York; Western General Dispensary, Hon. Secretary of; Wolverhampton General Hospital; Mr. E. T. Worley, Stony Stratford; Walsall Rural District, Medical Officer of Health, of; Mr. G. A. Wright, Manchester; Messrs. Wright, Dain, Peyton, and Co., Birmingham; Mr. C. Hamilton Whiteford, Plymouth, Miss Weston, Portsmouth; Mr. S. Wesley Wilson, Dublin.

Letters, each with enclosure, are also acknowledged from—

A.—Messrs. Allen and Hanburys, Lond.; Dr. E. Allen, Hawes; Messrs. Ayrton and Saunders, Liverpool; A. S. W.; A. M.; Dr. S. M. Alcantara, Los Teques, Venezuela; A. A.

B.—Mr. J. H. Booth, Chesterfield; B. F.; B. J.; Bridgwater Infirmary, Hon. Secretary of; Dr. A. H. Brehaut, Guernsey; Bourne Castle Sanatorium, Belbroughton, Secretary of; Mrs. *Behnke, Lond.; B. G.; Birmingham* General Hospital, House Governor of.

An original and novel feature of "The Lancet General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not onl affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in The Lancet.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies onl should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manage arles Good, The Lancet Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addresse e Lancet can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Adve ents are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières Paris.

A Clinical Lecture

ON

THE NATURE OF DISCHARGES AND DOUCHES.

Delivered at the Central London Throat, Nose, and Ear Hospital on Feb. 28th, 1901,

BY WYATT WINGRAVE, M.D. DURH.,
PHYSICIAN AND PATHOLOGIST TO THE HOSPITAL.

DOUCHES AND IRRIGANTS.

Purposes.—A douche or irrigant may have for its object: (1) the mechanical removal of morbid secretions, accumulations, and foreign bodies; or it may be used (2) for antiseptic purposes; or (3) for diagnosis.

Essentials.—To effect satisfactorily these objects the douche or irrigant must conform to certain requirements which vary according to circumstances. 1. The solution employed should, when practicable, be a solvent of the substance to be removed. 2. The reagent should be itself readily soluble in water and form a clear solution. 3. It should be non-irritating to mucous membranes and sensitive surfaces. 4. To ensure thoroughness it should possess the power of penetrating the surface tissues. 5. It should be miscible—i.e., chemically compatible with the most effective antiseptics. 6. It should be economical in cost and readily available. Of these essentials perhaps the most important one is that of having the power to dissolve the discharge, since there are so many solutions in general use which not only have no such solvent action but actually precipitate and harden the substances which they are intended to remove.

Nature and composition of discharges.—As a preliminary to choosing the materials for a douche it may be expedient to consider the nature and composition of the different discharges and accumulations which demand treatment. So far as our own field of work is concerned they may thus be grouped: (1) catarrhal; (2) serous; (3) purulent; (4) cerumen and cholesteatomata; and (5) fibrinous and hæmorrhagic.

1. Catarrhal products as commonly met with in the nose and naso-pharynx and less frequently in the ear may be either viscid or inspissated to the extent of forming "crusts." Coming from a mucous membrane the fluid consists chiefly of an alkaline solution of mucin, with globulin and serum albumin in proportions varying with the intensity and nature of the morbid process. Epithelial cells in varying degrees of mucoid degeneration, and leucocytes, will be suspended in the fluid, together with varieties of bacteria. Of the organic constituents mucin is readily soluble in weak solutions of alkaline salts, such as bicarbonate of sodium (from 0·5 to 1 per cent.), but insoluble in acids, while cells and serum globulin are soluble in weak solutions of neutral salts, as also the nucleo-albumins of the cells, albumin being soluble in water.

2. Serous discharges rarely call for special removal except when localised. In them globulin occurs in greater proportion than mucin, therefore a neutral saline solution should be selected.

3. Pus will obviously vary considerably according to the conditions of its production and the duration of its retention. It may be thin, viscid, and even solid (caseous), sweet or fœtid. According to Hoppe Seyler the proportions of organic solids in 100 parts of dried pus are: proteids, 13; nuclein, 34; fats and lecithin, 14; cholesterin, 7; cerebrin, 5; extractives, 4; and insoluble substances, 20. Halliburton gives nucleo-albumin, cell globulin, albumoses, and peptones as the chief constituents. In the fluid part or serum globulin with small quantities of serum albumin and albumoses will be found, while the organised solid or cell elements, such as leucocytes, connective tissue fragments, &c., will yield nucleo-albumin, cell, globulin and nuclein, also fats, lecithin, cholesterin, &c., in varying degrees of fatty and other degeneration. All these are soluble in weak solutions of either neutral or alkaline salts respectively.

4. Cerumen may vary from a thin treacly consistence to that of a firm plug, more or less mixed with epidermal squames, hairs, parasites, dust, and other foreign matter. Being fatty in nature it is readily soluble in alkaline salts. But as the duration of contact by an irrigant is so short and the plug oftentimes so dense softening by means of a strong alkaline solution, preferably in glycerine, is often expedient as a preliminary to the douche. Cholesteatomata consist of closely packed laminated squamous epithelium with fatty granules and cholesterin crystals. The cells will yield much keratin and nuclein, both of which with the fatty débris are soluble in alkalies. Sometimes, as in middle-ear suppuration, the epithelium is mixed with pus; if so the neutral salts also should be used in combination.

5. Plastic exudation consisting chiefly of filamentous fibrin entangling leucocytes in its meshes is extremely difficult of solution and rarely admits of more than a softening process by solutions of the neutral and alkaline salts, such as sodium sulphate, calcic hydrate, &c. The same applies to blood-clot, which is, however, less dense and consequently much more readily removed by similar irrigants.

Choice of material for douche.—Knowing the nature of the discharge and the solvents of its chief constituents there will be but little difficulty in selecting an efficient irrigant which shall act both chemically and mechanically. The appended table of reagents in frequent use will facilitate selection. On one side are grouped the solvents, on the other those which either actually precipitate, or at all events do not dissolve, the prevailing constituent of the discharge.

Table of Solvents and Precipitants.

Solvents.	Precipitants.
Sodium sulphate (from 1 to 2 per cent.).	Water (except albumin).
Potassium (from 1 to 2 per cent.).	Mercury biniodide.
Magnesium (from 1 to 2 per cent.).	Mercury perchloride.
Ammonium (from 1 to 2 per cent.).	Alum.
Sodium bicarbonate.	Zinc chloride.
Sodium chloride.	Zinc sulphate.
Sodium hydrate.	Zinc permanganate.
Sodium biborate.	Potassium permanganate.
Sodium sulpho-carbolate.	Hydrogen peroxide.
Calcium chloride.	Formalin.
Calcium hydrate.	Carbolic acid.
Potassium hydrate.	Boric acid.
Potassium carbonate.	Liquor sodii chlorinat.
Chinosol.	Liquor carbonis detergens.
	Izal.
	Alcohol (fats excepted).
	Sulphurous acid.

It will thus be seen that many of the solutions which we most usually employ are not those best adapted to their purpose, since some of them—e.g., the salts of mercury, phenol, boric acid, &c.—actually coagulate or form insoluble compounds with the chief constituents of the discharge, thereby preventing thorough irrigation. One must not ignore, however, the qualification that the duration of contact between the irrigant and the discharge is often so short that either complete solution or complete precipitation of the organic elements can scarcely be expected. Still, it will generally be quite sufficient for the purpose if the matrix is dissolved and diluted so as to facilitate the division and removal of the solid and organised matter—e.g., in the case of "crusts," caseated pus, cerumen, cholesteatomata, &c. This will obviously be more thorough when a solvent of that matrix is employed in preference to a fluid which can at the best act only mechanically. It is scarcely necessary to discuss each agent separately, yet several demand special notice.

Taking water first, this is by no means the most effective irrigant, whether employed as tap or distilled, warm or cold, since of the organic substances albumin is about the only one which it dissolves.

Next in importance are the neutral salts—sodium, potassium, magnesium and ammonium sulphates with sodium and calcium chlorides. These act as solvents of the globulin group but vary in degree and according to the strength of solution employed. Sodium sulphate is by far the most useful, especially if employed in a strength of from 1 to 2 per cent., but if stronger—e.g., from 5 to 10 per cent. or more—it causes precipitation of proteids. It still further has the property of penetrating organic tissues. This is well illustrated in the action of Müller's fluid (a solution of chromic salts and sodium sulphate) which not only hardens the tissue but penetrates to its deepest part. Should the chromic salts be used alone, however, the hardening is only superficial. This quality is of the greatest value when dealing with a granulating surface and in economising cocaine.[1] Sodium sulphate still further has the valuable property of mixing readily with biniodide and other salts of mercury in efficient antiseptic strengths. Calcium chloride, although not quite so good a solvent, is particularly useful as a hæmostatic douche, since calcium salts play an indispensable part in the blood coagulation. Sodium carbonate is perhaps the best solvent of mucin which forms by far the chief organic substance in catarrhal secretions, it is also a solvent of nucleo-albumins, fatty materials, nuclein, keratin, &c.; its strength should be about 0·5 per cent. The same remarks apply to borax (sodium biborate), which salt has the additional advantage of possessing some antiseptic properties. Its strength should be from 0·5 to 1 per cent. Sodium, potassium, and calcium hydrate are valuable chiefly for their softening action upon the tissues and are not applicable as douches except in very weak solutions since they form a glutinous compound with albumins known as Lieberkuhn's jelly, familiar to us in the well-known "ropy" or "gelatinous" reaction between pus and liquor potassæ. The first and second are useful when combined with glycerine for softening ceruminous and epidermal plugs as a preliminary to irrigation. Chinosol does not precipitate and mixes well with the neutral salts, but decomposition occurs when combined with alkalies. Distilled water is preferable to tap water.

We will now consider the behaviour of the opposite group, which apart from their purely passive and mechanical action in very weak solutions are either actual precipitants or at all events do not dissolve the matter which they are employed to remove. As before mentioned, pure water precipitates the globulins and has no solvent action upon fats; used alone therefore it is not an entirely efficient douche. The salts of zinc—sulphate, chloride and sulphocarbolate and permanganate—are chiefly used for their astringent properties, since they form insoluble compounds with the proteids and should only be used as astringents. The same applies to alum and to potassium permanganate. The latter salt may be mixed with sodium bicarbonate or biborate and forms an excellent douche for removing fœtid crusts in the nose and naso-pharynx Boric acid is perhaps one of the most favoured douche agents, probably owing to its supposed antiseptic qualities, but, unfortunately, it is not a solvent of proteids and therefore does not conform to our essentials. Carbolic acid (phenol) is a powerful precipitant of the proteids; it should therefore be mixed with solutions of sodium sulphate or carbonate, when it will prove a more efficient douche. Care must always be taken that the solution is complete, otherwise the phenol will be simply suspended and will obviously cause much irritation, even pain, especially when used as a nasal douche. Imperfect solution can be avoided by using the best preparations of phenol (absolute or No. 1 carbolic acid) by boiling, by using the above salts, or by diluting glycerine of carbolic acid (P. B.). Formalin is now very popular as a douche but it is a very powerful precipitant. Peroxide of hydrogen, unless freely diluted, has the great disadvantage of causing rapid effervescence when mixed with pus. This is extremely awkward when irrigating a cavity such as the maxillary sinus. Izal and liquor carbonis detergens are not only precipitants but have the further disadvantage of being emulsions and opaque, so interfering with diagnostic evidence. They are also toxic and very irritating to the mucous membranes and require great care in their use. Finally, the inorganic salts of mercury—the perchloride and biniodide—are most powerful precipitants, readily forming insoluble compounds with albumins and globulins.

In addition to its purely mechanical use a douche may be required for antiseptic purposes But our most valuable antiseptics are precipitants of proteids and therefore not thorough irrigants; consequently, it is more often expedient to irrigate first with a solvent and use the antiseptic afterwards, as in the case of suppurative middle-ear disease. This need not, however, always be done, since biniodide of mercury, phenol, chinosol, and many powerful antiseptics are not only miscible with pure sodium sulphate but when mixed the solution does not precipitate proteids so readily as a plain solution of the antiseptic would. This is a property of no slight importance. In the use of potassium permanganate where there is much mucin, as in the crusts found in atrophic rhinitis, a combination with sodium bicarbonate or biborate will be found to afford a very efficient deodorant douche with or without sodium sulphate. Boric acid is so feeble an antiseptic, even by itself, that its combinations need no serious consideration. This, however, does not apply to chinosol which, mixed with sodium sulphate, affords not only a clear solution but one having high solvent and antiseptic properties. Its great disadvantage is its cost. Sanitas also mixes well with the neutral salts and its efficiency is markedly increased.

It will thus be seen that few reliable antiseptics when used by themselves actually conform to the essentials of a perfect douche, but when combined with a neutral salt their efficiency is undoubtedly increased, this being due in a great measure to an increase in penetrative power.

A protesting word may here be not superfluous with regard to many popular formulæ combining thymol, eucalyptol, menthol, and other aromatics with various inappropriate salts which are employed as antiseptic douches. These are not only extremely irritating to the mucous membrane—especially the nasal—sometimes causing great discomfort, but their solvent and antiseptic properties are so problematical that they should only be recommended as deodorants and in those cases which demand stimulating as an adjuvant to the routine solvents—e.g., atrophic rhinitis. When available an economical and efficient douche in cases of atrophic and fœtid rhinitis is to be found in sea-water. It should be thoroughly well boiled, decanted, and used at a temperature of about from 60° to 70° F. A pinch of sodium bicarbonate to the pint may be added when the crusts are very firmly adherent. When employed for diagnostic purposes the douche should be transparent and colourless, hence liquor carbonis detergens, creolin, izal, permanganates, &c., are to be avoided. Likewise, too, it is inadvisable to employ any precipitant such as mercuric chloride for exploratory irrigation when the exit passage is likely to be minute—e.g., per Leichwitz cannula in the case of suspected maxillary sinus disease.

Although far from complete the foregoing selection may be considered as fairly representative of the materials frequently employed as douches, and however true it may be that experience eventually leads us to select that which is most serviceable the application of our knowledge of physiological chemistry will doubtless not only facilitate that selection but also guide us to still further improvements. While disclaiming any intention of suggesting a universal irrigant, experiments in the laboratory and clinical observation amply emphasise the fact that we have in the neutral salts, especially sodium sulphate, by far the most reliable basis for an irrigant, especially when pus predominates, but in many instances already referred to the addition of an alkaline salt will render it even more effective. Whatever formula be employed it must obviously be modified according to the clinical circumstances calling for its use and efficiency will be ensured by practically appreciating the teachings of the physiological laboratory.

The appended formulæ are based upon the foregoing principles, having all been thoroughly tested chemically and clinically, and although selected chiefly for use in connexion with diseases of the ear and upper respiratory tract they are equally applicable to general surgery.

Formulæ.

1. Sodium sulphate, from one and a half to three drachms; water to one pint (20 fluid ounces), from 1 to 2 per cent.

2. Sodium sulphate, from one and a half to three drachms; sodium bicarbonate, 40 grains; water to one pint.

3. Sodium sulphate, from one and a half to three drachms; borax, 40 grains; water to one pint.

4. Sodium sulphate, from one and a half to three drachms; sodium bicarbonate, 40 grains; glycerine of carbolic acid, 45 drops; water to one pint.

Note.—Instead of glycerine of carbolic, absolute phenol nine grains or No. 1 carbolic acid may be used. Heat to 155° F.

5. Borax, 40 grains; bicarbonate of soda, 40 grains; glycerine of carbolic acid, 45 drops; water to one pint (diluted Dobell's solution).

---

[1] THE LANCET, Dec. 8th, 1900, p. 1679.

reading the correspondence upon anti-vivisection as it appears in the *Times*—a correspondence which really throws remarkable sidelights upon the controversy because of the many minor issues which have been debated by the various writers—we have come to the conclusion that as far as the medical profession is concerned indifference is still the proper position. The anti-vivisectionists believe what they wish to believe, and those of them who are actively concerned in endeavouring to convert others to their view seem to regard all contradiction by the medical profession as the base attempts of a blood stained crew to escape chastisement for their deeds of callous brutality We have never imputed similar depravity to the anti-vivisectionist leaders, even when we see them maligning their superiors in knowledge or trying to wreck the labours of the truly charitable. We know their ignorance of the scientific work that has been done and of the scientific reasons that have led to the doing of it, their ignorance of the enormous alleviation of human ill that has directly followed physiological research in connexion with the lower animals, their ignorance even of the meaning of the physiological terms which they are bold to employ These are the things which make it impossible for the medical man to argue with anti vivisectionists of the more rabid order. And it is just because medical men are too closely interested in the question and possessed of too special a knowledge to be the proper people to traverse the anti-vivisectionists' conclusions that we welcome the assistance of the lay papers—the organs of public opinion. A medical man may be an authority upon a neurological point, but he cannot discuss it with a man ignorant of neurology Medical men, again, are at least as good judges as are their critics of what is right and what is humane, they have as just an appreciation of the place which the lower animals should fill in our lives as has any official of an anti vivisection society But as it is the morality of medical men and that of their professional leaders that is impugned their general testimony, like their scientific testimony, is not of great avail The well reasoned views of the lay press enable the public to grasp the real issues of the question.

The *Times* and other influential journals refuse to credit the suggestion that a large body of well-educated men engaged in work ancillary to a profession which is admittedly existent entirely to alleviate human pain, have *become callously and brutally cruel* as a class and as individuals. The conditions under which physiological experiments are now made constitute reasonable safeguards against cruelty Even if the monstrous supposition that all physiologists were animal torturers held good the laws of the land are sufficient to prevent such cruelty from being habitual. Against these statements we have the propaganda of the anti vivisection societies. There can be no doubt on which side public intelligence will range itself Despite the noise which the anti vivisection societies occasionally make their recruits are neither numerous nor inclusive of any men of high intellectual standing Excellent soft-hearted people they would appear to be, hating only common sense and physiologists. We trust that the result of the correspondence in the *Times* will be to give some of their leaders pause. There are the names of a few influential persons upon the lists of patrons whose actions might be copied by their social inferiors. We would ask them to consider if they honestly think that humanity demands the institution by anti vivisectionists of an organised attack upon the funds of the London hospitals? If they think so let them continue to support the sentimentalists.

Annotations.

"Ne quid nimis."

THE OBSTETRICIAN—PHYSICIAN OR SURGEON?

A CONTROVERSY is now going on at the Lincoln County Hospital bearing upon the old question as to how far an obstetric physician is justified in doing major surgical operations in a hospital. The facts are as follows Some two years ago a gentleman was elected to the staff of the hospital as physician. Sundry gynæcological cases having been admitted under his care he has been in the habit of performing minor operations, such as curettage of the uterus, although remonstrated with by the senior surgeon. Recently this physician gave notice that he was about to perform an oöphorectomy, whereupon the surgical members of the staff, excepting the senior surgeon who chanced to be away, pointed out that hitherto it had always been the custom for such operations to be performed by the surgeon for the week in which the patient chanced to be admitted. A memorandum to this effect, signed by the whole staff except the senior surgeon and the physician in question was handed in to the weekly board and this board decided that it was not outside the province of a physician to perform gynæcological operations. The matter is now to be referred to the quarterly board of governors which will meet on April 10th The medical staff of the hospital has ascertained the practice at 35 other provincial hospitals comparable in size and in other respects to their own, and in all of these major gynæcological operations are handed over to the surgeons, although in some hospitals minor operations such as curettage are performed by the physician. It seems to us that the matter is not one in which there can be any hard-and fast rule. To take the case of London. In all the big hospitals gynæcological and obstetrical cases are under the charge of a physician who has nothing to do with ordinary medical cases. In some of these hospitals all gynæcological operations are performed by the obstetric physician, including such as involve a laparotomy In others the obstetric physician performs only such operations as curettage, operations on the cervix uteri, or repair of vesico-vaginal fistulæ, while operations involving a laparotomy, such as *oöphorectomy, hysterectomy, operations on the tubes*, and the like, are handed over to one of the surgeons, either to the surgeon of the week or to that member of the surgical staff who is definitely appointed for the purpose. In regard to the position at Lincoln we think that precedent should be followed until such time as a new rule is made, not merely by a weekly board but by the governing body of the hospital, including the staff. The physician in question when appointed to his present post either knew the custom of the hospital or he did not know it. If the former he has no right to alter the position which he knowingly accepted, if he accepted the post in ignorance of the customs governing it he again has no right to alter the terms of his tenure on his own initiative.

LONGEVITY

IN an article entitled "Modern Methuselahs," published in the *Evening Standard* of March 19th, reference is made to a man named Michael Solis who in 1878 was living in Bogota,

6. Sodium sulphate, one and a half drachms; chinosol, 10 grains; water to one pint.

7 Sodium sulphate, one and a half drachms; sanitas, three fluid drachms; water to one pint.

8. Sodium sulphate, one and a half drachms; perchloride of mercury, two grains; water to one pint (1 in 5000).

9. Sodium sulphate, one and a half drachms; red iodide of mercury, two grains; sodium iodide, two grains; water to one pint (1 in 5000).

10. Sodium sulphate, one and a half drachms; potassium permanganate, two grains; water to one pint.

11. Sodium bicarbonate, 40 grains; potassium permanganate, two grains; water to one pint.

Note.—Borax (40 grains) may be used instead of sodium bicarbonate.

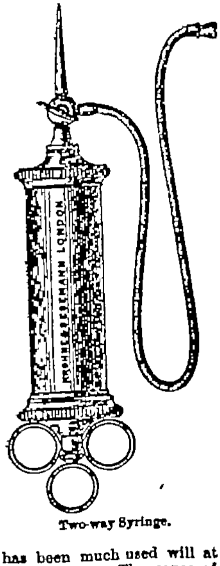
12. Solution of calcium chloride (P.B.) six fluid drachms; water to one pint.

Notes.—The pure exsiccated sulphate of sodium should always be used in preference to the ordinary crystalline salt. Bicarbonate is preferable to carbonate of sodium. Hot water whenever convenient should be employed to make the solutions. Solutions of phenol should be heated to 155°. No. 1 as a simple irrigant for pus, Nos. 2 and 3 when mucus is present or when the discharge is inspissated, Nos. 4, 5, 10, and 11 for inspissated fœtid mucus or "crusts," Nos. 6, 8, and 9 as antiseptics, and No. 7 and 10 as deodorants. No. 12 is chiefly employed for its hæmostatic property.

METHODS OF EMPLOYMENT AND INSTRUMENTS.

The selection of an instrument will be guided, first, by the particular purpose for which the douche is to be employed; secondly, whether it is intended for the surgeon's or for the patient's sole use. This distinction is by no means unimportant, knowing how rarely the layman appreciates the possibility of infection and the importance of cleanliness. In this instance he is perhaps not entirely to blame, since the ordinary apparatus at his disposal—e.g, the rubber ball, glass or metal syringes—are without doubt the most dangerous weapons ever employed An ocular and olfactory, still more a bacterial, examination of the interior of any syringe which has been much used will at once emphasise the truth of this statement. The cause of this is obvious · no apparatus that has to be filled by the aperture which comes in contact with the wound can escape contamination of its interior except through special care which cannot be expected in its domestic employment. In the case of aural and nasal douches the application to the nozzle of a short piece of rubber tubing which can be renewed or removed and sterilised greatly reduces the risk of infection or of injury during self-use. The ordinary form of hydrostatic douche is not liable to infection in this particular way, but it is a somewhat clumsy arrangement and not to be advised for delicate and deliberate work as in aural cleansing, since it admits of but slight variation in volume and pressure.

FIG 1.

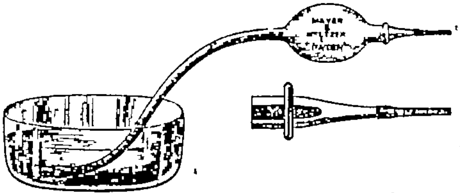


Two-way Syringe.

Dr. J. Dundas Grant's modification of the piston syringe is thoroughly efficient in guarding against septic infection, being fitted with a two-way tap which admits of filling through a separate channel (Fig. 1) This with the ordinary piston glass or metal form is, however, very difficult for the patient to use himself.

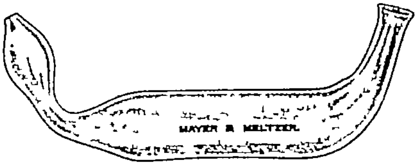
The writer's aseptic douche (Fig. 2) will be found specially adapted to this purpose, since the patient not only has force, direction, and volume of fluid directly under control, but by means of inlet and outlet valves the irrigator can only be filled at the distal end like a Higginson's syringe, of which it is in fact a modification. It is very wide in its application but is specially valuable in cases of disease of the ear requiring great care in auto-irrigation and those forms of rhinitis demanding a copious douche The glass nasal douche (Fig 3) is particularly useful when small quantities only are required.

FIG. 2



Aseptic Aural and Nasal Douche. Nozzle, showing valve.

FIG. 3



Glass Nasal Douche.

It is as unnecessary to describe in detail all the numerous forms of apparatus adapted to special purposes as it is to enumerate and to condemn all those which do not conform to the most rudimentary principles of cleanliness, but it may not be unreasonable finally to emphasise that no apparatus can be safely employed in which one aperture serves both for filling and for emptying

---

DEVON AND EXETER DENTAL HOSPITAL.—The twenty-second annual meeting of the subscribers of this institution was held at the Guildhall, Exeter, on April 25th, under the presidency of the sheriff. The report showed that 2778 patients were treated during 1901. The financial statement was satisfactory The late Mr. R. West had bequeathed £1000 which will be placed to the reserve fund which has been opened for providing new premises for the hospital.

HEALTH OF GLOUCESTER.—Dr. J. Campbell, the medical officer of health of the Gloucester Urban Sanitary Authority, in his report for 1901, which has just been published, states that the estimated population at the end of 1901 was 48,473. There were 647 deaths during the year—i.e., 13 3 per 1000, the lowest rate ever recorded for the locality 1378 births were registered, giving a birth rate of 28 4 per 1000, the lowest for the past 10 years, this being due in part to the previous under-estimation of the population 154 deaths occurred in children under one year of age, corresponding to an infant mortality of 111 7 per 1000 born, as compared with an average of 144 8 for the 10 preceding years.

A Clinical Lecture
ON
SEPTIC POLYARTHRITIS.

Delivered at the Manchester Royal Infirmary on Jan. 23rd, 1902,

By G. A. WRIGHT, B.A., M.B. OXON., F.R.C.S. ENG.,

SURGEON TO THE ROYAL INFIRMARY; PROFESSOR OF SYSTEMATIC SURGERY IN THE OWENS COLLEGE.

GENTLEMEN,—We have in the wards at the present time three patients suffering from what I may call "septic polyarthritis" and it is of certain forms of this class of disease that I propose to speak to-day. I will take the reports of two of these first, with that of another from Scotland, and we can then consider the questions arising from a study of them.

CASE 1.—Our first patient is a married woman, aged 35 years, who was admitted on Oct. 3rd, 1901, suffering from "stiffness of all her joints." She had good health until her first and only confinement in July, 1895. Her child was stillborn. Seven weeks after delivery the small joints of the hands and wrists became swollen, inflamed, and painful, and within four months both great toes had been similarly attacked. She stated that after her confinement she suffered from a continuous purulent vaginal discharge and in 1896 she was for six months in hospital under treatment for this uterine trouble. The discharge, however, continued and towards the end of 1896 her feet and ankles became swollen and inflamed. By June, 1897, the abovementioned joints had become fixed and about this time the knees, cervical spine, and jaws became acutely swollen, the hips and shoulders were also attacked, and by the close of 1897 she was rendered completely helpless by the general rigidity of her joints. She now had marked thickening of the skin of the soles and palms with desquamation and rapid loss of hair. During 1898 her condition seems to have been unchanged and there was still slight vaginal discharge. In the autumn of 1899 "hot-air treatment" was employed. The vaginal discharge ceased at this time, her condition improved, and she was again able to feed herself. From this date to the time of her admission to hospital she began gradually to improve as regards movements of the jaw, neck, and hands, though she was still bedridden. On admission the general nutrition was fairly good, the movements of the spine showed little impairment, the mouth could only be opened to the extent of one inch, and lateral masticatory movements were abolished. The large joints of the upper extremities were enlarged, their mobility was restricted, and the skin covering them was smooth and somewhat reddened. There was no distinct synovial effusion but marked thickening of the joint structures. There was distinct grating on rotation of the shoulder-joint. The wrists were stiffer than the elbows and movements of pronation and supination were almost lost. Both hip-joints were involved to some extent. Both knee-joints were swollen, indurated, and partially fixed in flexion, the right being stiffer than the left. The ankles were much less affected. The hands and feet were more especially crippled. There was a flabby, toneless puffiness of the backs of the hands and fingers, leaving the knuckles marked by depressions; the phalangeal joints were much stiffened, the terminal ones least so. The feet were in much the same condition as the hands.

For the notes of the next case I am much indebted to Dr. Cowan of New Galloway, N.B., who kindly sent them at my request. I had repeatedly seen the patient at her home in Scotland during annual visits to the neighbourhood.

CASE 2.—The patient, a single woman, now aged 29 years, was a perfectly healthy girl until the age of 24 years and was in service. One day during a menstrual period she had a heavy day's washing and felt cold. The next morning the left knee was swollen and painful. In spite of treatment the knee got worse and she had to leave her place. At this time the disease was thought to be tuberculous. Treatment was continued and after a year she was in the Edinburgh Royal Infirmary for a time and the knee was fixed. The joint was apparently kept at rest in one way or another for many months and then massage was employed. The other knee became painful and swollen and later the fingers of the right hand, the right ankle, and then all the other joints of the limbs in rapid succession. She has been confined to bed for five and a half years and has changed little during the last two years. She has had some inflammation about the toe-nails. Opium was given at one time with apparently good effect, though now she is fairly comfortable without it. "She has now (1902) no motion in any joint and is unable to move any of her limbs in the very slightest." "All that she can do is to move her head and even that motion is limited." "The elbow joints are the most swollen and glossy and often ooze a watery fluid." She has had some irregular menstruation but never any leucorrhœa.

CASE 3.—The third patient is a single woman, aged 22 years. She has a tuberculous family history. When she was about 14 years old she had leucorrhœa which lasted almost without intermission till about 12 months ago. She was admitted to hospital on Jan. 1st, 1902, complaining of pain and swelling in the right ankle. About three years ago the left foot and ankle suddenly became very painful and swollen. She was in bed for three weeks and was quite well in a month. Three or four months later the right foot became swollen and painful and has remained so ever since, though the swelling is not so great as it was. At first the inflammation was acute and the skin was red and hot, but after a few days the active symptoms passed off, only the pain remaining. The wrists and left shoulder have also at times become swollen and painful and the right calf has latterly been much swollen and very tender. The patient is very anæmic. There is a somewhat pulpy swelling pushing forward the extensor tendons of the right ankle; there is also a little œdematous thickening over the malleoli, with slight swelling on either side of the tendo Achillis. Movement is limited and is accompanied by crackling. There are a good deal of pain and tenderness but there is no redness about the joint. There is also pain in the left ankle and left wrist and in the right metatarso-phalangeal joint but no visible change in the appearance of these joints. The right calf is somewhat œdematous and very tender. There was a slight vaginal discharge on admission which ceased after a few days' treatment.

A study of these three cases shows us, first, an affection which attacks many joints though it may begin in a single joint, which lasts for a long time, even years, which may give rise to the most complete crippling, which shows no tendency to cause extensive suppuration or even suppuration at all, which may leave a joint intact, which may subside and recur repeatedly, and which does not give rise to any nodular, bony, or cartilaginous outgrowths, or to hydrarthrosis. In this disease soft parts other than joints may be inflamed and the skin and nails may be apparently the seat of trophic changes. The general health of these patients has not been gravely impaired.

Since it is not perhaps quite generally recognised that these conditions are due to the cause which I assign for them we may consider for a moment what possible relationship they may have. Acute rheumatism may be rejected at once. "Rheumatic arthritis" may be excluded without much difficulty since there are no osteophytic growths or hydrarthrosis and neither the course of the disease nor the implication of non-articular structures would support a diagnosis of this hotch-potch of unclassified joint troubles. A diagnosis of chronic rheumatism does not take us any further; nor does, perhaps, a statement that the condition is a neuropathy. We sometimes see conditions of joints closely resembling these as sequelæ or complications of typhoid fever. We have in the wards now a girl, 11 years of age, who was admitted suffering from acute necrosis of a metatarsal bone after a blow. This child has pain, swelling, and stiffness of her ankles, knees, and hips, with evidence of septic endocarditis, and is clearly suffering from a condition that no one would, I think, hesitate to call acute septic arthritis. I need not describe her case because the condition is well known and familiar and undisputed, but it very closely resembles the others except in the more severe degree of poisoning that exists in this child. The possibility of the mischief being due to syphilis might be considered in one of the cases but not in the others, and it is not, I think, a probable explanation.

---

[1] Based upon notes of cases taken by Dr. T. L. Fennell, house surgeon, and Mr. A. Hodgkinson and Mr. A. Hodge, dressers, and upon others supplied by Dr. J. Cowan of New Galloway, N.B.

An acute tuberculous joint disease is worth thinking of and I am not at all sure that in Case 3 the ankle is not tuberculous. In some of these cases that I have seen I have been *strongly impressed with the possibility of tubercle being* a factor and have thought that the mischief might be due to a mixed tuberculous and other process. It will have been noticed that Case 2 was evidently treated as tuberculous at one time.

In May of last year Dr T. K. Monro of Glasgow published in the *British Medical Journal* an account of one of these cases occurring in a young man after frequent wettings. He refers to a paper by Dr J Griffiths in which there is a full discussion of the morbid anatomy of ankylosis, but unfortunately the histories are not in sufficient detail to enable us to draw any certain conclusions as to the etiology of the disease.

Now I have no doubt that all these cases are instances of septic arthritis—i.e., are directly due to absorption of one or other of the ordinary septic organisms from some unhealthy or enfeebled area. We have seen how the condition may be produced as the result of an acute septic periostitis—in the pus taken from this case staphylococci alone were found. There are plenty of records of similar cases in which injury or the depressing effect of cold and wet have lit up acute infective processes. We know of course that gonorrhœal rheumatism, so-called, produces exactly similar conditions and Dr Griffiths mentions that in three of the cases which he collected gonorrhœa was considered to be the exciting cause of this ankylosing arthritis, and it is quite a familiar fact that without any obvious suppuration septic arthritis is specially likely to end in a stiff joint. I take it, then, that two of these cases are instances of ankylosing leucorrhœal polyarthritis, one in a far advanced and one in an early stage, and that Case 2 is a similar condition due to absorption of poisonous material from the genital tract by reason of disturbance of the menstrual process by cold and fatigue. A menstrual synovitis is mentioned by Barwell who also mentions such a condition arising during pregnancy One of Dr Griffiths's cases was also possibly due to disordered menstruation. Dr E. J Cave of Bath read a very *interesting paper, mentioning various sources of infection,* at the meeting of the British Medical Association last year

We can hardly go so far as König and say that 90 per cent. of cases of acute arthritis are due to urethritis, but I do wish you to carry away with you two ideas. The first is that slight uterine disorders, such as leucorrhœa, very commonly indeed give rise to troublesome joint inflammations which do not get well until the absorption of the poisonous material is checked and that in a doubtful case of joint disease the probability of some such cause should be carefully considered. The second idea is that such cases if neglected may go on to the production of such terrible crippling as we have in two of the cases which I have mentioned, in one of which you have seen the patient. I think that you will often be able to recognise these cases by the peculiar indurated condition of the peri-articular tissues which exists after the acute stage is over if the mischief has been at all severe.

I do not want you to think that there is anything new or far-fetched about what I have said. It is all quite well known but it is not sufficiently remembered in examining cases of joint disease. The channels of absorption of septic material which is specially apt to infect joints perhaps from their close relationship to lymphatic structures, such as serous sacs, are manifold. The conjunctiva (Lucas), the digestive tract, the bladder, &c., as well as those which I have mentioned to you to-day, have all been shown to be liable to act as paths for the entrance of septic material to joints, and the same thing is probably true as regards septic bone diseases.

As to treatment I will not say much to-day. The great point, of course, is to get rid of the septic focus as quickly as possible. As regards the joints, rest and soothing applications at first, with massage, inunction of oleate of mercury, and a course of iodide of potassium later, are probably the best measures. In these, as in most cases of stiff joints, active movement is of much more value than is passive movement. I exclude, of course, in this statement the question of localised adhesions.

Though in one of the patients "hot-air treatment" was credited with a great deal I am inclined to think that the cessation of the leucorrhœal discharge was a much more important factor in the improved conditions. The great thing is to recognise the cause of the mischief.

THE DIAGNOSIS OF MALARIA FROM THE STANDPOINT OF THE PRACTITIONER IN ENGLAND.[1]

BY PATRICK MANSON, M.D ABERD., F.R.C.P. LOND., C.M.G., F.R.S.

SLIPSHOD diagnosis is not to be commended. We must confess, however, that so far as the interests of patients are concerned, in the vast majority of diseases, provided the physician abstain from a too active interference with natural processes, it matters little whether diagnosis be exact or even correct. In too many diseases we possess little or no power for good. Fortunately for the reputation of our art there are a few diseases over which we can exercise absolute or relative control, and just because we possess in the case of these remediable diseases this power it is of the utmost importance that we recognise them—that we diagnose them accurately The disease about *the diagnosis of which I propose to offer a few remarks this* evening—malaria—is one of these. For it in quinine we possess an almost infallible remedy Hence if we fail to recognise malaria when it is present, and in consequence of such failure in diagnosis omit to administer the appropriate remedy, the patient suffers and we grossly fail in duty. Contrariwise, if in some given case we erroneously diagnose malaria and treat the patient accordingly we certainly treat the case wrongly, perhaps miss the chance of cure by more appropriate means, waste a valuable drug, and certainly run the *risk of damaging our own reputation. The ability to* diagnose malaria is therefore a matter of high practical importance.

In those countries in which malaria is endemic and common it not infrequently happens that the infection is overlooked. As a rule, however, it is the other way about, malaria is far too frequently assumed to be present where it has nothing whatever to do with the case. This remark is equally, if not more, applicable to certain cases of disease which come to England from abroad. Such is the exaggerated idea of the insalubrity of tropical countries, of the universal prevalence of malaria in them, that a very large proportion of the febrile and even non-febrile diseases coming from them to this country are diagnosed and treated as malarial. It happens far too often, both in England and in the tropics, that the practitioner when in difficulties about a tropical patient assumes the case to be malarial. The patients likewise are very prone to be content with, and to endorse, such a diagnosis, for they, too, from one cause or another have come to believe that in the matter of disease "tropics" *spells "malaria." Somehow,* to many there seems to be a sort of fascination and appropriateness about the word "malaria," as if it carried with it mystery, romance, and explanation such as is said to belong to the blessed word "Mesopotamia." In the course of 12 years' experience of London practice I have seen some two or three cases only in which malarial infection had been overlooked. In the same time I have seen a very large number of cases in which malaria had been diagnosed but in which malaria was neither present nor had anything whatever to do with the symptoms The latter type of case I meet with so *frequently that I thought,* when asked to read a paper before this society, I could not do better than choose for my subject this very practical matter of the diagnosis of malaria as we find it when imported into England.

Whatever *may* have been the difficulties in the way of reliable diagnosis of the infection in the past, recent discovery has enabled us to be precise and absolutely sure about it—at all events in 99 cases out of 100 There are few diseases so easily diagnosed; nevertheless, although nearly every member of the profession knows in an academic sort of way the principles on which the points of diagnosis are founded, my experience tells me that these principles are not applied systematically or in actual practice assessed at their proper value. Possibly it may serve some useful purpose if, availing myself of this opportunity, I recapitulate and accentuate these principles. The pathognomonic indications of malarial infection may be conveniently arranged under these headings: (1) the clinical; (2) the therapeutic; and (3) the microscopical.

---

[1] Delivered before the Medical Society of London on May 12th, 1902.

1. *The clinical diagnosis of malaria.*—There are many signs and symptoms of malarial infection—fever, anæmia, icteric tinting of skin and scleræ, enlargement of the spleen and liver, gastro-intestinal disturbance, and a tendency to spontaneous recovery and to subsequent recurrence. All or any of these may lead one to suspect, but not one of them, nor the concurrence of all of them, justifies a positive diagnosis of, malaria. None of them and no grouping of them is pathognomonic. They are present separately or variously combined in many other morbid conditions. They may justify in any given case a suspicion, but not a diagnosis, of malaria.

There is only one clinical symptom that justifies a positive diagnosis. This is periodicity—periodicity of a particular type—tertian or quartan periodicity—a rhythmical recurrence of symptoms every 48 or 72 hours. In no other morbid condition are these to be found and wherever they are well marked malaria is present.

In malarial disease the appearance of quotidian periodicity is common enough but it is only the appearance. It is very doubtful if true quotidian periodicity ever occurs in malaria. If it does it is certainly very rare. The parasites of malaria are either tertian or quartan in habit and many of the symptoms which they give rise to are correspondingly tertian or quartan in their recurrences. Multiple infection by two kinds of parasites or by two or three generations of the same series of parasite may give rise to double tertian or treble quartan infection with diurnal recurrence of symptoms, but this pathologically, whatever it may be clinically, is not a true quotidian periodicity. It is common enough in malaria but I would insist that it is not pathognomonic of malaria, for a similar quotidian periodicity is very general—in fact, it is usual—in almost all febrile complaints. Therefore, to make quotidian periodicity a ground for a diagnosis of malaria is wrong. More than that, it is most dangerous and is, perhaps, the commonest cause of erroneous diagnosis of malaria. Experience has made me formulate a rule for myself which I commend to you—have absolute confidence in tertian and quartan periodicity as a basis for a diagnosis of malarial infection, but distrust, or rather absolutely disregard, quotidian periodicity

In tropical practice I have seen more mistakes from relying on quotidian periodicity as a ground for diagnosing malaria than from any other cause. The temptation to attach weight to it is often very strong but I would again urge on you to harden your hearts against it.

When a patient from the tropics comes to you with a story of evening rigor, rise of temperature to 103° or perhaps 104° F., and a profuse sweat the idea of malaria naturally presents itself. Most probably the patient tells you that he has malaria. And if one finds the patient anæmic and that his spleen is large—perhaps very large—the diagnosis of malaria seems to be clinched. But people abroad get splenic and spleno-medullary leucocythæmia and other diseases in which the spleen is enlarged as well as people in England, and such patients often have marked quotidian fever. These leucocythæmic and other kinds of enlarged spleen cases I frequently see on the supposition that they are malarial. Had the patients never been abroad probably the idea of malaria would never have been entertained.

Another type of case in which there is enlargement of the spleen associated with anæmia and quotidian fever I occasionally see, probably because it, too, is sometimes supposed to be malarial. In a sense the cases I refer to are malarial—or, rather, post-malarial. I allude to what is known in Assam where the condition in certain districts is very common and very fatal—as Kala azar. The same condition occurs in other malarious countries, however. The patient gives a history of malarial attacks which at first were controlled to some extent by quinine. After a time the recurring attacks became more frequent and less amenable to quinine. Finally, the fever resisted treatment, became quotidian, the spleen becoming permanently enlarged, the anæmia intense, the skin sallow or even melasmic, and ultimately, in spite of treatment, the patient, if not cut off by some intercurrent disease, dies from pure anæmia. This disease, although possibly induced by malaria, has long ceased to be malaria—it is, in fact, a post-malarial cachexia brought about by organic changes in the blood organs and induced possibly by some additional and distinct infection attacking organs already damaged by antecedent malaria. I find that the presence of enlarged spleen is a bait that few resist when attempting the diagnosis of a quotidian fever in a patient from the tropics. The combination is so suggestive. But we must bear in mind that many people in the more malarious districts in the tropics have, though free from active malarial disease, chronically enlarged spleen, and we must also bear in mind that the possession of an enlarged spleen is no protection against other diseases and that enlarged spleen is symptomatic of many diseases, febrile and other. I have several times seen ulcerative endocarditis in patients with spleens enlarged from antecedent malaria in coincidence merely. The same occurrence I hav often seen in phthisis and in many septic conditions.

If quotidian fever associated with enlargement of th spleen is to be distrusted as a combination indicative o malaria, still more so is quotidian fever associated with enlargement of the liver. The latter combination usually means abscess of the liver. Anyone who has had much experience of tropical practice must know that this disease is often, I might say generally, at all events in the earlie stages, diagnosed malarial fever. Osler says he had seldom seen an abscess of the liver in which the patient had not been liberally dosed with quinine. This is my experience likewise Strange to say, syphilis, both secondary and tertiary, is no infrequently, on the strength of an associated quotidian feve and a residence or visit to a malarious country, diagnosed malaria. Septic absorption of pent-up pus is a well-recognised cause of quotidian fever not unfrequently attended with marked rigor and diaphoresis. Sometimes the most carefu examination fails to determine the situation of the pus. Now if suppuration of this description occurs in an individua who has resided in malarious countries the case is almos sure to be diagnosed malaria. I have seen many such cases. Pyelitis, catheter fever, pylephlebitis, empyema phthisis, middle-ear disease, elephantoid fever, the feve of early leprosy, the fever sometimes associated with gall-stones—these and many similar conditions occurring in patients from abroad, because they are accompanied by an ague-like quotidian fever and because they occur in individuals who have been abroad, are constantly being diagnosed malaria and treated as such. Therefore I say in approaching the diagnosis of a pyrexia in a possible malaria while regarding tertian and quartan periodicity as absolutely conclusive attach no weight whatever to quotidian periodicity.

2. *The therapeutic diagnosis of malaria.*—Whatever may be the case in certain malignant infections in tropica countries quinine, properly given, so far as my experience goes, never fails to arrest a malarial attack occurring in this country, and this within 48, or at most 96, hours of its administration. Therefore a periodic or remitting fever that persists after adequate dosing with quinine, say for four days, is not malarial. Everyone believes, or says that he believes, in the anti-malarial virtues of quinine, but it is strange how little confidence some practitioners have in its diagnostic value Thus I frequently see in consultation patients with fever presumed to be malarial who have been taking quinine in large doses for weeks or even months, and yet no suspicion about the correctness of diagnosis had been entertained. When asked to see a case of supposed malarial fever of a persistent nature my first question usually is, "Has the patient taken quinine, for how long, and in what doses?" If I am told, as is often the case, that he has had large doses for many days I feel sure, without seeing the case, that it is not one of malaria. In this country if any of you are called on to treat a fever you suppose to be malarial, and if this fever resists quinine properly given and in full doses for three or four days my advice to you is to revise your diagnosis; the fever is not malarial. I could quote many cases in illustration; it is hardly necessary to do so.

There are two important matters, however, which require to be attended to in applying the quinine test. First, the dose must be adequate. Second, the quinine must be absorbed. In many instances quite an insignificant dose will check an ague. Many years ago while in practice in the island of Formosa I ran short of quinine and had to economise my very limited stock. With this object I experimented to ascertain the minimum dose that would check an ague and ultimately came down to half a grain three times a day. My Chinese patients in several instances said that they were cured by this insignificant amount—so potent is quinine in some cases of malaria.

This winter I had in hospital a patient suffering from double benign tertian infection. By a properly timed small dose of quinine it is sometimes possible to eliminate in such a case one group of the parasites without injuring the other group and so to convert a quotidian ague into a tertian. I wished to demonstrate this to the students at the School of Tropical Medicine. I gave the patient three grains of quinine an hour or thereabouts before an expected paroxysm. Small though the dose was it killed out, not only the group of parasites which I proposed to eliminate, but the other group as well, and cured for the time being the patient.

Quinine as against the malaria parasite is a very potent drug but for reliable diagnostic, as well as for therapeutic, purposes it must be administered in much larger doses than those I have just mentioned. I would say that if a fever in this country resists 10 grains of quinine given three times a day for four days it is not malarial.

The dose of quinine should not only be adequate but we must assure ourselves that it is absorbed. I am quite certain that many of the failures to control malaria by quinine are attributable to neglect of this essential. A catarrhal state of the gastric mucous membrane is usual in severe malarial attacks; such a condition is very unfavourable to absorption. Persistent vomiting is also common enough; food and drugs are alike rejected. To get the therapeutic action and diagnostic value of quinine in such circumstances the drug must be given hypodermically or by enema.

Quinine nowadays is often given in tablet or coated pill form—a most dangerous method in serious cases and a most unsatisfactory one for diagnostic purposes. For some time quinine tablets have not possessed the flint-like hardness that used to characterise them a few years ago; they are now more soluble, but even lately twice I have seen them fail to be absorbed. In one case the patient developed a severe malarial attack on his way home from the Gold Coast. He took quinine tablets and persisted in their use after his arrival in London. So much quinine did he take in this way without benefit that both the patient and his medical attendant lost confidence in the drug and the patient came very near dying. Three or four intra-muscular injections of the acid hydrochloride broke the fever and the patient quickly recovered. In giving quinine, therefore, whether for therapeutic or for diagnostic purposes we should assure ourselves that it is absorbed.

3. *Microscopical diagnosis of malaria.*—Of the three means for diagnosing malaria this is the most satisfactory provided it is undertaken by one with large experience. A negative result by the amateur is valueless: a positive result is not much more to be trusted. It takes a large amount of practice to be able to recognise all forms of the malaria parasite or to discriminate between them and vacuoles in the red corpuscles in fresh films, or dirt in dried and stained films. Articles in the medical papers by amateurs in malarial blood examination sometimes supply amusing reading. The frequency with which such writers encounter malarial rosettes and flagellated bodies and free flagella, forms of the parasite least frequently met with, is very suggestive. Free pigment—in reality, dirt—they often see. White blood corpuscles I have known described as malarial parasites, blood platelets as spores or sporulating parasites, and cotton fibres or fibrin as flagella. No one without some knowledge of the histology of normal blood and much experience of microscopical examination of malarial blood should attempt to write on the subject of the malarial parasite, much less attempt responsible diagnosis of malaria with the microscope. The thing is easy enough when one has been properly taught and after large experience. Then the microscope is invaluable in diagnosis, but those who have not been so taught and who have not had much experience are eminently unreliable—they are often worse than useless. Therefore, for the majority of medical men, if they wish to have blood examined for the purpose of diagnosis in regard to the presence of a possible malarial infection, the services of an expert are necessary But although he may not be able himself to diagnose malaria with the microscope every medical man should know how to prepare blood films suitable for such an examination. Very singular notions are entertained about this. I have sometimes had blood sent me in capillary tubes such as are used to hold vaccine. I have also had sent me blood so thickly smeared on a slide that the preparation would not transmit light. I have also had sent me from a distance an ordinary slip and cover-glass wet preparation with a request to examine it for malaria. Blood transmitted in any of these ways is useless. Unless the fresh blood can be examined at the bedside or within an hour or thereabouts of preparation dried films should be made and subsequently transmitted to the laboratory for fixing, staining, and microscopical examination

There are many ways of preparing malarial blood-films I have tried most of them The best, I believe, is that described by Dr S R. Christophers and Dr. J W. W. Stephens or some modification of this An ordinary microscope slip is carefully cleaned with alcohol. The patient's finger-tip or the lobe of his ear is similarly cleansed. The finger or the ear is then pricked with a clean and rather long ordinary sewing needle. A drop of blood is pressed out and, as it may contain epithelial débris, wiped away. A second but very minute drop of the size of a large pin-head is then expressed and touched lightly (the skin must not be touched) with the clean surface of the slip about an inch from the one end. Immediately the shaft of the needle is laid transversely on the droplet of blood so transferred to the slip. After waiting a second or two for the blood to run out by capillarity between the surface of the slip and the needle, the latter, held between finger and thumb, is drawn along the surface of the glass. In this way with a very little practice a beautifully fine and even film is produced. Half a dozen such films should be prepared The single prick suffices as the films can be made very rapidly one after another. After they have dried they should either be wrapped in very clean tissue paper or placed in a dust-free slide-box and transmitted to the laboratory. Here they are fixed with alcohol *(five or ten minutes) and subsequently stained and examined.*

For purposes of diagnosis I use either borax methylene blue or dilute carbol thionine. These are very reliable stains, keep well, act rapidly, and give sufficiently good results. Undoubtedly one of the several modifications of Romanowsky's stain when successful gives a more brilliant picture, but they are somewhat unreliable, and unless the particular sample of stain employed is in frequent use and known to be good this method is not advisable for ordinary purposes of diagnosis. Leishman's modification of the Romanowsky method gives very beautiful results and has the advantage of not requiring a preliminary fixation of the blood with alcohol, but it, too, has the objection of unreliability in ordinary clinical conditions. Malarial blood should not be fixed by heat.

In stained films, or in fresh blood, it is practically always possible to find the parasite, at all events in those cases of malarial infection that come to England. But this only on one condition, and this condition I would impress on you—the patient must not have taken quinine recently. You may find certain forms of the parasite—the crescent, for example—after full dosing with quinine, but the usual fever-causing forms, as a rule, rapidly disappear after administration of the drug. Therefore, if you wish to have a reliable microscopic diagnosis in supposed malarial fevers do not give quinine, or suspend its use for some time, before preparing the blood slides.

In rare instances and at certain times in a considerable proportion of cases the parasite, or its product melanin, even in severe infections may not be detectable in the peripheral blood, and, as I have mentioned, even small doses of quinine therapeutically in sufficient doses may cause its disappearance temporarily or in the case of cure for good Even in these circumstances it would seem that the microscope may be relied on for a diagnosis

It has been known for some years that during and for some time after malarial attacks the leucocytes are greatly diminished in proportion to the red blood corpuscles. The diminution, however, is principally in the polymorphonuclear and lymphocytes, so that there is a relative increase in the large mononuclears. Dr Christophers and Dr. Stephens, fixing their attention on this point, have marked out a method by which it is possible to give a fairly reliable diagnosis of actual or recent malarial infection and this no matter whether quinine has been administered or not. The increase in the mononuclears they state is principally during the apyretic intervals setting in as soon as temperature begins to fall. They say in a report to the Royal Society that "an increase beyond 15 per cent. is proof of an actual or recent malarial infection." Captain L. Rogers, I.M S., after a very careful investigation of the point, endorses[2] this opinion. He concludes: "An increase in the large mononuclears to about 12 per cent. and upwards, especially during the remissions of the temperature, strongly indicates malaria."

---

[2] Brit. Med. Jour., April 5th, 1902.

Dr. C. W. Daniels, superintendent of the London School of Tropical Medicine, has paid a great deal of attention to this point. In reply to a request for a statement of his views he writes: "*Leucocytic variation after malaria.*—In all forms of malaria after and to a smaller extent during the fever the large mononuclear leucocytes are relatively increased to the other leucocytes. This increase may be slight and in certain cases has been so slight that they only formed 15 per cent. of the leucocytes. Commonly after malaria they vary from 25 to 30 per cent. and occasionally are over 40 per cent. The increase does not seem to be dependent on the species of parasite, or the number of parasites present during the acute attack, or on the severity of the symptoms or sequelæ. It is maintained for a period varying in different cases from two or three weeks to at least as many months and slowly diminishes. It is not affected by quinine either in large or frequently repeated doses. With some exceptions it affords a satisfactory proof of the probable recent presence of parasites. In normal blood it is rare to find more than 12 per cent., though I have seen as high a percentage as 16. In typhoid and Malta fever I have seen a similar increase but it is exceptional. It is said to occur in small-pox. In certain diseases, particularly scurvy, there is also a marked increase but in this disease there is also leucocytosis and a more marked increase in the lymphocytes. The absence of this variation is of more value as a diagnostic point than its presence. As far as I have worked with the method the only exceptions I have seen were when an intercurrent disease, such as pneumonia, which is associated with increase in the polymorphonuclear elements, also occurs. In other cases it has shown itself to be a reliable method for the exclusion of recent malaria. Working for three sessions with classes of students of 20 odd, many of whom coming from the tropics have suffered from malaria, this test has readily discriminated those of the students who have recently had malaria from those who have not. It has proved of value in differentiating cases of yellow fever from malaria (Low and Gray in St. Lucia). It has proved of value in differentiating the hyper-pyrexial fever of West Africa from malaria (Sims, Congo). Though not of the same value as the presence of parasites or of pigmented leucocytes or recent pigment in the organs, it is of much higher value as a test of recent malaria than splenic tenderness or enlargement and is of particular importance in cases where either in the natural course of events or after the administration of quinine there are no characteristic symptoms. It is probably of about the same value as the agglutination test in typhoid with moderate dilutions of the serum, say, 1 in 20. The main objection to the method is the difficulty that is sometimes present in deciding which are large mononuclears and which are lymphocytes. After actual practice this difficulty is small and a column for undecided or doubtful leucocytes will be found useful at first. After a short time this will be in the majority of cases little used. In these determinations, however, there is a certain personal equation so that counts made by different individuals vary within small limits." These are Dr. Daniels's opinions and being based on large experience I attach much value to them.

We sometimes get assistance in concluding for or against malaria from considerations of time and locality. It is very commonly believed that a malarial infection may last a lifetime. Thus the old Indian, many years after he has come home for good, may tell us that he has recurrences now and again of a jungle (that is, malarial) fever contracted in youth. I do not believe in the malarial nature of such attacks. I have never been able to find the parasite in any such case. My belief is that malarial infection does not persist after three years from the date of invasion—of course, a patient can become reinfected, that is another affair; but I do not think the duration of any given infection exceeds three years. I will not be positive about this. We want more observations. But in my experience a malignant tertian tends to die out in from 18 months to two years, a benign tertian in about from two to two and a half years, and a quartan in about three years We know that other protozoal organisms having asexual and sexual phases require resuscitation by passing through the sexual phase every now and again; otherwise they become extinct. I believe the same to be the case with the malarial parasite. Other people besides the old Indian get feverish colds and different kinds of short febrile seizure, but because they had never been in India or Africa they call them influenza or what not. Had the old Indian never been to India he would do the same. He is rather proud of his jungle fever and sticks to it longer than it sticks to him. While alive to the possibility of my being wrong in my belief I am inclined to regard any fever which occurs three or more years after the patient has been away from the possibility of fresh malarial infection as non-malarial. If a patient has never been to a malarial country he cannot get malaria unless by artificial or abnormal means. In the malarial belt there are many non-malarial places—Malta, for example. A chronic or recurring fever from Malta in a person who has not visited a malarial place is probably Malta fever or enteric fever, certainly not malaria. Similarly, Barbados is not malarial. Therefore a chronic or recurring fever in a patient from Barbados who has never visited a malarial place cannot be malarial—most probably it is the fever symptomatic of some of the lesions in filariasis so common in Barbados. Commonly enough, because such fevers are ushered in by severe rigor these filarial fevers are locally known as "ague." This is a misnomer; they have nothing to do with malaria.

I have a good many reputedly malarial patients from the fen districts and other formerly malarious spots in England. On critical examination not one of them has turned out to be malarial. They were assumed to be malarial because there was some periodicity about the fever, perhaps enlarged spleen, and because they came from localities which were formerly malarious. I have never seen a case of indigenous English malaria. I believe the plasmodium has died out in England like the wolf and the wild boar.

In concluding these rambling and disconnected, but I trust practical, remarks I would again impress on you the importance of a thorough reliance on these three classical methods of diagnosing malaria: the clinical—tertian and quartan periodicity; the therapeutic—the curative effect of quinine; and the microscopical—the detection of the parasite or its products in the blood and the characteristic leucocytic variation. A thorough and intelligent application of one or all of these methods seldom, if ever, fails to lead to a correct diagnosis for or against malaria. At the same time I would warn you that although a positive diagnosis of malaria may be indicated in some given case the presence of malaria does not exclude other diseases. On the contrary, malaria often predisposes to other infections. Similarly, the explosion of a latent malaria is favoured by other infections, especially typhoid fever and tuberculosis.

REMARKS ON THE SUBSEQUENT HISTORY OF CHILDREN BORN WHILST THE MOTHER WAS INSANE.

By A. F. TREDGOLD, L.R.C.P. Lond., M.R.C.S. Eng.,
FORMERLY RESEARCH SCHOLAR OF THE LONDON COUNTY COUNCIL.

Whilst engaged upon an inquiry in 1900 into the causes of idiocy and imbecility I incidentally came into contact with a considerable number of women who, whilst actually suffering from an attack of insanity and under detention in an asylum, had given birth to children, and it occurred to me to trace, if possible, the subsequent history of these children. This seemed all the more desirable because, as far as could be gathered, no special attention had previously been given to the subject, although an impression prevailed generally amongst asylum medical officers that most of the children so born were illegitimate and stillborn (which impression the inquiry showed to be erroneous). Further, it was hoped that information bearing upon the subjects of heredity and maternal impressions might also be obtained. Want of time prevented me from proceeding with the inquiry then but it has now been completed and the results are given in this paper.

It was first of all necessary to obtain some idea of the number of children born under these conditions, and even a simple inquiry of this kind was by no means an easy matter owing to the absence in many asylums of any special record of births. However, through the kindness of the medica superintendents of the London County Asylums at Cane Hill, Colney Hatch, and Claybury I eventually obtained a list of 121 women who had given birth to children whilst under treatment in those institutions.

My object was to ascertain whether the mental and physical development of these children were in any way abnormal and, if so, whether any connexion could be traced between such abnormality and the condition of the mother during pregnancy. For this, data of three kinds were necessary—viz., (1) of the subsequent history of the child; (2) of the age, variety and duration of insanity of the mother; and (3) of the family history of both parents. In each of these directions great difficulties presented themselves. The children having been passed on to the workhouse or to friends were particularly difficult to trace; many of the mothers had either died in the asylum or, having recovered from the attack of insanity, had been discharged and lost sight of; and the class from which pauper lunatics are drawn being of pronounced migratory habits it will be readily understood that the difficulty of obtaining a satisfactory family history of the father was even greater. However, by personal inquiries, correspondence, and industrious searching through the case-books a large number of accurate details were finally obtained. But unfortunately it frequently happened that where a good account of the child was forthcoming up to a considerable age the particulars of the parents were defective, and *vice versâ*, so that the determination to include only those cases in which full data were obtainable led to a great reduction of the material and by the time the cases were put together the 121 originally started with had dwindled down to 38 (13 males and 25 females). It is to be regretted that it was not possible to gather together a larger number but considering the nature of the inquiry this was perhaps only to be expected and it is believed that the extreme care which has been taken to insure accurate and complete details will in a great measure compensate for the paucity of material. The results obtained, moreover, are so uniform and they corroborate so completely my observations while investigating the causes of idiocy and imbecility that I do not think that a larger number of figures would affect the deductions.

THE CHILDREN.

First of all, then, let us consider the subsequent history of the children. With regard to their mental and physical condition they readily fall into two groups: (1) those who are alive and of good mental and bodily development, of whom there are 13; and (2) those who are dead or are mentally affected, of whom there are 25. The healthy children comprising the first group have, with one exception, been traced beyond the age of two years, so that they fairly may be considered as having arrived at the stage at which any pronounced marks of degeneracy or mental or physical abnormality would have shown themselves; indeed, the larger number of them are now going to school and are to all appearances bright, intelligent, and normal in every way. In the second group, those dead or mentally affected, all are as a matter of fact now dead, although some of them lived long enough to show definite signs of mental abnormality. Further, close examination shows that the majority in this group succumbed quite early in life, as is seen from the following figures:—

Stillborn	3
Died under the age of 1 month	5
" " 2 months	7
" " 3 "	4
" " 6 "	1
" " 1 year	2
" " 2 years	1
" " 3 "	2
Total	25

It is thus shown that no less than 22 out of the 25 children were dead before the first year. This, then, gives an infant mortality (under one year of age) of 22 out of 38, or 580 per 1000, amongst children born whilst the mother was insane—truly an alarming figure when we remember that the infantile mortality in the most thickly-populated parts of London averages only 225 per 1000[1] and is in many parishes much less, and the conclusion would naturally be that the mental condition of the mother does indeed have a very important effect on the subsequent condition of the child; such a view, however, as will immediately be seen, requires very considerable modifications.

THE MOTHERS.

Turning now to the mother, it has to be ascertained whether any connexion exists between her age, the variety of insanity, the length of time the attack has lasted, the presence of any morbid heredity as revealed by her family history, and this abnormally high mortality of the children. The age of the mothers varied from 18 to 46 years. The variety of insanity was generally mania or melancholia (mania predominating), but general paralysis, delusional insanity, and primary amentia also occurred. In some cases the attack had first made its appearance when the pregnancy was approaching its termination, in others it had existed since the fourth month. After a very careful *examination into each of these possible factors* I have come to the conclusion that no connexion whatever can be traced between any of them and the subsequent condition of the child. This indeed appears to be more closely related to the number of attacks of insanity through which the mother has passed or to their nature as regards recovery or otherwise, since in those instances in which previous attacks have occurred or where the insanity has become chronic the percentage of unsatisfactory children is much greater. It must, however, be remembered that recurrent attacks of insanity are more often associated with a morbid heredity and this brings us to the consideration of the family history, in which I believe the true explanation of this high mortality lies.

MORBID HEREDITY.

In order to study the influence of morbid heredity upon the child the family history of both parents must be inquired into, though since we are studying cases in which the mother is actually insane it obviously follows that the maternal antecedents of these children are much more likely to be tainted than the paternal. I have found it the most convenient plan to arrange the cases in five groups dependent on the degree of morbid heredity present, as the effect upon the children can then more readily be observed. These five groups are as follows:—

TABLE I.—*Showing the degree of Morbid Heredity present.*

CLASS A.—MORBID HEREDITY NEGLIGIBLE (10 children living and four children dead)

Group I.—Eight Children Alive and Four Children Dead.

Mother.—Insanity present in the child's mother only, her antecedents and collaterals being healthy.
Father.—*Nil.*

Group II.—Two Children Alive.

Mother.—In addition to the child's mother being insane, insanity or epilepsy is also present in her brothers or sisters but the antecedents are healthy.
Father.—*Nil.*

CLASS B.—MORBID HEREDITY WELL MARKED (three children living and 21 children dead).

Group III.—Three Children Alive and 13 Children Dead.

Mother.—In addition to the insanity of the mother it is present in *one* previous generation of either her maternal or paternal ancestors.
Father.—*Nil.*

Group IV.—Four Children Dead.

Mother.—In addition to the insanity of the mother it exists in either *two* preceding generations on one side or in *both* her maternal and paternal ancestors.
Father.—*Nil.*

Group V.—Four Children Dead.

Mother.—Any of the preceding groups.
Father.—Insanity, alcoholism, or phthisis strongly marked.

It will be seen that in the first group, save the actual insanity of the mother, there is no morbid heredity (by which I mean insanity, pronounced alcoholism, or phthisis). In the second group insanity is present in the collaterals of the mother, but the most searching inquiry fails to find it or other injurious influences in her antecedents, the child's paternal antecedents being also untainted. I think that we may therefore place these two groups together in one class and consider that in them the morbid heredity is practically *nil*. In this class there are 14 cases,[2] of whom 10 are at present alive and apparently perfectly normal, and four are dead; of these four, however, one was quite healthy until the age of two and a half years when he succumbed to bronchitis, so that it is open to question whether this child should not really be placed in the satisfactory group of children; and in two others of these four

---

[1] Ninth Annual Report of Medical Officer of Health of the County of London, 1900.

[2] Actually there are only two cases in Group II., as against 12 in Group I.

TABLE II.—A SYNOPTICAL TABLE SHOWING THE RELATION OF MORBID HEREDITARY INFLUENCES TO THE SUBSEQUENT HISTORY OF THE CHILD.

The Numbers in the Squares refer to the Cases.

—	Children alive and of normal mental and bodily condition, traced as far as the age stated.				Children dead at the age stated.							
Class A.—No morbid heredity.	1 9 years.	2 4 years.	5 7 years.	7 4 years.	14* 3 weeks.	21 3 months.	28* 2 months.	43† 2½ years.				
	8 2 years.	27 7 years.	29 4¼ years.	32 3 years								
	40 13¾ years.	41 15 years.	Total, 10.								Total, 4.	
Class B. — Morbid heredity present.	6‡ 2 years.	10 5 years.	20‡ 3 months.		3§ Under 2 years.	4 3 weeks.	9 2 hours.	11 3 months.	15 7 weeks.	16 Stillborn.	17 2 months.	18 1 hour.
					22 2 months.	24 1 month.	26 6 weeks.	31 2 months.	33 6 months	34 7 months	35 2 months.	36 10 weeks.
			Total, 3.		37 Immediately after birth.	38 Stillborn.	42 3 months.	44 9 months.	45‖ 3 years.		Total, 21.	

* Mother strongly alcoholic; no heredity; defective vitality of child probably due to mother's *physical* condition. † Died from bronchitis; previously normal. ‡ Slight heredity on mother's side only (Group III.). § Died from disease of the brain. ‖ Died from wasting disease of the brain.

children the insanity of the mother was brought about by excessive indulgence in alcohol (in one case assisted by semi-starvation), so that I think it is justifiable to conclude that in these the diminished vitality and early death of the child may really be attributed to the *physical* state of the mother during the ante-natal period, especially as I have elsewhere shown[3] that the physical state of the mother during this period exerts an important influence upon the child.

The next three groups (Groups III., IV., and V.) may likewise be placed together in one class, in which morbid heredity is present. In Group III. insanity exists in a previous generation of either the paternal or maternal ancestors of the child's mother; in this group there are 16 children, three of them being alive and 13 dead. In Group IV. insanity exists in either two preceding generations on one side or in *both* the paternal and maternal ancestors of the child's mother; in this group there are four cases, all the children being dead.

In none of the above groups is there any morbid taint on the child's paternal side.

Lastly, in Group V. are placed those cases in which, in addition to the insanity of the mother, well-marked morbid heredity is transmitted to the child through its *paternal* progenitors, and in this group, therefore, I regard these hereditary influences as being at their maximum. Here also there are four children, all being dead.

So that, briefly to summarise these results, we find that in Class A, in which morbid heredity may be considered to be absent, there are 14 children, 10 of whom are alive and four dead; and in Class B, in which such heredity is present, there are 24 cases, three of the children being alive and 21 being dead. The accompanying table emphasises these points and shows also the period up to which each child was traced (Table II.).

It has been mentioned that some connexion seems to exist between the subsequent history of the child and the number of attacks of insanity from which the mother has suffered or their nature as regards recovery or otherwise. That this, however, is due to the fact that recurrent attacks, or insanity which passes into a chronic and incurable condition, are usually those in which strong predisposition exists is ily seen from Table III. In it are two groups—(1) the mothers who have been discharged recovered; (2) those who have either died insane in the asylum or have become chronic lunatics. The letters A and D refer to the condition of the child as being alive or dead, the figures underneath denoting the number of the case.

TABLE III.—*Showing the Relation of the Mother's Heredity to her Subsequent History as regards the Attack of Insanity.*

—	No morbid heredity in the mother's antecedents.	Morbid heredity present in the mother's antecedents.
Mother discharged recovered.	A. A. A. A. A. 1 7 27 40 41 D. 21 Total 6.	A. A. 10 20* D. D. 26 35 Total
Mother died insane or became a chronic lunatic.	A. A. A. A. A. 2 5 8 29 32 D. D. D. 14† 28† 43‡ Total 8.	A. 6* D. D. D. D. D. D. D. D. D D. 3 4 9 11 15 16 17 18 22 24 D. D. D. D. D. D. D. D. D. 31 33 34 36 37 38 42 44 45 Total 20.

* Heredity only slight. † The mother's insanity due to alcohol. ‡ The child died at the age of two years and six months from bronchitis; previously healthy.

From this table it is seen that out of the 14 mothers in whom no hereditary predisposition occurred six were discharged as recovered (five children being alive and one dead), whilst eight either died insane or passed into a condition of chronic insanity (five children alive and three dead), whereas out of the 24 mothers in whom hereditary predisposition occurred only four were discharged recovered (two children alive and two dead) and 20 died insane or became chronic lunatics (one child alive and 19 dead). I think that this clearly shows that although a large number of mothers may become insane during pregnancy in the absence of any hereditary taint and that in many of them the insanity is not recovered from, the condition of the child is not thereby influenced but is only related to the presence or absence of morbid heredity. Whether these

* The missing numbers are those of cases which are not included owing to the particulars being imperfect.

United States of Colombia, South America, and at that time claimed to be 184 years old. The writer goes on to say that "there is very little doubt about this remarkable case. THE LANCET investigated it thoroughly in 1878, and came to the conclusion that the man was at least 180 years old then." This is evidently an over-estimate of the attention which we have given to this particular instance. The facts are that in our issue of Sept. 7th, 1878, p. 343, we mentioned the current rumour on the subject and spoke of the man's alleged age as "offered for our credence." Moreover, a fortnight afterwards—namely, on Sept. 21st, at p. 427—we published a letter from Dr. W. L. Dudley of Cromwell-road, South Kensington, who had resided for over 20 years in Bogotà and had been physician to the General Hospital and to the British and American Legations. This gentleman wrote to us that, speaking within his knowledge, he would judge that the age of this individual, six years before the date of writing, was between 80 and 90. He added that longevity was rare in these districts and that there was no baptismal or other kind of registry in the city. Readers in search of "records" of longevity may perhaps be gratified by the perusal of Mr. Charles W. De Lacy Evans's "Can We Prolong Life?"[1] reviewed in THE LANCET of June 21st, 1879, p. 884. An antidote to Mr. Evans's extravagancies will be found in the first half of Mr. T. E. Young's interesting and scientific summary of the present state of knowledge on this subject.[2]

THE KING'S CORONATION DINNER TO THE POOR.

LENT being over it is natural that the thoughts of men should turn to feasting. His Majesty the King, as we announced in THE LANCET of March 22nd, p. 840, has signified his intention of giving a dinner to 500,000 of his poorer subjects so that they may share the joy of the coronation in a tangible form. The money for this feast is at hand, supplied by His Majesty from his own purse, the food is easily obtainable, and there will be no lack of guests. But to bring the food to the right persons will call for powers of organisation scarcely inferior to those at present demanded by the situation in South Africa. In 1897 we expressed our opinions as to the carrying out of the Jubilee dinner organised by the gracious lady who was then Princess of Wales. In our issue of May 22nd, 1897, p. 1423, we said:—

> We have no details at present as to how the scheme of feeding these poor people is to be carried out, and in our opinion a vast amount of careful organisation will be required if the project is not to end in failure. That there is a terrible depth of bitter poverty in London no one can doubt, but as a rule it is just the most deserving who hide their misery and prefer to suffer in silence. Will any steps be taken to seek out the really deserving and, more important still, will there be any attempt to confine the dole to the poor of London alone? If something of this kind is not attempted every scoundrel or loafer—all those who have never done any work and never mean to do any—will come from all parts of the kingdom and batten on the charity provided. This was the case some years ago when the Mansion House famine fund was started; the metropolis was inundated with provincial tramps and there was great doubt as to whether the really needy profited at all. Another matter of vital importance is the likelihood of the spread of infection by the gathering together of those who owing to their mode of life are most prone to contract and disseminate infection. The revelations made some year or so ago by Dr. Waldo about Salvation Army shelters showed that even under ordinary circumstances the crowding together of the homeless was anything but free from danger and such danger will be multiplied a thousandfold in the coming month. The most careful watch should be kept upon all lodging-houses and workhouses on the roads leading into London as well as in that city itself and we think that some attempt should be made to see that the food supplied does not go to fill the bellies of those who make a trade of poverty.

We have no wish to pose as alarmists and so far as statistics show no increase in the number of cases of infectious disease for 1897 could be traced to the crowds assembling for the Jubilee celebrations. But still the risk has to be thought of and precautions should be taken, for owing to the increase in population and the world-wide interest taken in the coronation all the points of difficulty which we have mentioned above exist with even more force to-day than in 1897, more especially in face of the small-pox epidemic, as regards the danger of the spread of infectious disease. It would be well, we think, if some method could be hit upon of excluding those who have not resided in London for a certain time—at least since Christmas Day, 1901—but perhaps this check would be impossible to impose. In the meantime, we can but await details of the organisation by means of which the scheme is to be carried out.

THE STAGES OF THE MALARIA PARASITE AND THEIR TERMINOLOGY.

PROFESSOR LANKESTER has devised and communicated to the Royal Society a set of terms applicable to the complicated series of stages through which the parasite causing malaria passes during its life-history in the mosquito and in ourselves. The aim is that the terms made use of should explain themselves; and, accordingly, such vague and barely explanatory terms as "sporozoites" and "blasts" are dropped out of use and replaced by a new set which have the merit of serving as a *memoria technica* to the student desirous of remembering the manifold changes exhibited by the sporozoön of malaria. We may conveniently commence with Professor Lankester at the spore which is injected into our blood by the bite, and with the saliva, of the anopheles. This spore, a minute needle-shaped particle, is formed in the gnat's body, and as we naturally look upon the most important stages in its life as being those which are passed in our bodies the name of "exotospore" may be applied to this acicular spore as indicative of its origin *outside* our bodies. These spores ultimately enter each one of them a red blood corpuscle, though the actual mode of their entry has not yet been observed. Arrived within the blood disc they lose the acicular shape and become amœbiform. For this stage the expression "amœbula" is used. The amœbula grows and moves about as far as possible within the blood corpuscle; finally it breaks up into a number of spherical spores which are set free by the destruction of the red blood corpuscle. To these spores, the third stage in the life-history of the sporozoön, the term "enhæmospores" is applied by Professor Lankester. The term signifies, of course, that they are formed within the blood of the infected human being. The enhæmospores remain in this condition for several generations, entering other corpuscles and multiplying by further division. It is this process which infects the whole body with the parasite. After a certain time, which varies, and owing to conditions which have not yet been ascertained, the enhæmospore ceases to break up into fresh enhæmospores but grows largely in size and becomes different in shape. This stage is commonly crescentic in form; it still remains within the red blood corpuscle which loses its pigment; the pigment is devoured by, and undergoes slight alterations in colour within the body of, the sausage-shaped or crescent-shaped parasite. This is designated the "crescent" or "crescent-sphere." This fifth stage, the "crescent," is to be differentiated from those which have been already considered by the important fact that it is sexual, but no means exist of distinguishing the male from the female crescents, except, of course, their subsequent behaviour. It is, moreover, the last stage which we find in the human body. Arrived at this stage the parasite can undergo no further development unless it is sucked up by a mosquito. When this latter event happens the crescents become rounded and from the one kind, the male, develop spermatozoa much in the fashion after which they develop in the sperm mother-cells of the earthworm—that children in later years evince any special tendency to become insane I am unable to say and it is doubtful whether a sufficient number of children could be followed far enough in life to enable this question to be satisfactorily answered. It is, however, abundantly clear that up to the age at which it has been possible to trace them they in no way differ from ordinary children. This fact is of considerable interest in connexion with "maternal impressions," for it would be difficult to conceive of a more profound mental change than is frequently present in the insanity of pregnancy, ranging as it does from the most violent and acute mania to a melancholia almost approaching stupor and yet, as has been seen, the child may be perfectly normal.

---

[2] On Centenarians. London. Charles and Edwin Layton. 1899.

Many authorities hold the view that the mind of the mother *is* capable of exerting an influence upon the developing embryo, but I cannot but think that the facts here given are strongly opposed to any such view, and, as far as my own personal experience goes, all that I can say is that in the investigation of nearly 200 cases of idiocy and imbecility I was unable to find evidence in a single instance of the operation of any such influence, although it must be admitted that such was frequently alleged.

On the other hand, it is plainly evident that when a strong morbid heredity exists the vitality of the child is so much impaired that its chances of surviving more than a few months are small, and I am convinced that this morbid hereditary influence plays a very important part in the *degeneration of the offspring and finally culminates in either* idiocy or extermination.

Incidentally it may be noted that abnormalities of parturition do not occur with any greater frequency in these cases than in the outside population Three children were stillborn and one was born prematurely, but the remaining 34 births were normal in every way and of the whole 38 only seven were illegitimate.

In view of the preceding facts I do not see what other conclusions can be drawn than that (1) the mental and physical condition of the child is in no wise influenced by the mere fact of the mother being insane during pregnancy, (2) neither is the condition of the child influenced by the variety of insanity, the duration of the attack, or the age of the mother, nor even directly by the number of attacks from which the mother may have suffered, but that (3) *this condition is directly dependent upon the presence or absence of morbid hereditary influences*

Guildford Surrey

LIQUID AIR AS A FREEZING MEDIUM IN THE LABORATORY.

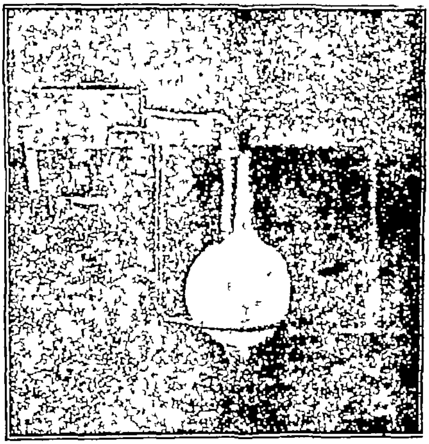
BY W H. B STODDART, M.D, M.R.C.P LOND.,
ASSISTANT MEDICAL OFFICER, BETHLEM AND BRIDEWELL ROYAL HOSPITALS.

FOR the past month or so I have been using liquid air instead of ether as a freezing medium in the laboratory at the Bethlem Royal Hospital and I have found the advantages to be so great and the results so satisfactory that I have no hesitation in commending its general use to other pathologists.

Liquid air is obtained by mechanical compression of ordinary atmospheric air to one eight-hundredth of its volume and by removal of the impurities by fractional solidification. It is a fluid like water in appearance but of lower specific gravity It boils at a temperature of − 312° F and therefore at the temperature of the atmosphere when placed in ordinary vessels It evaporates, however, quite slowly when stored in the vacuum flasks used by the manufacturers An untouched gallon evaporates from the storage flask in about six weeks. In ordinary constant use in the laboratory a gallon lasts a little longer than a fortnight Liquid air is therefore very much cheaper than ether for laboratory purposes. Further it acts much more rapidly than ether—*about from 20 to 30 compressions of* the indiarubber bulb are always sufficient to freeze the gum and the tissue remains frozen much longer On the other hand, tissues are not destroyed by liquid air freezing more than by ether freezing. Lastly, the unpleasant smell of ether is done away with and instead thereof a *supply* of pure air issues from the microtome. I have had an opportunity of inspecting the impurities removed from the atmosphere in the process of manufacture of liquid air and have observed that the stench from these is worse than that from the worst London fog I regard this supply of pure air as most important; it makes pathological work much more pleasant and healthy. When working with liquid air the best method of ventilation for the laboratory is to shut all the windows and ventilators and to be satisfied with the pure air issuing from the microtome. It is no exaggeration to say that after a morning's work in the laboratory with liquid air I have felt as if I had been for a blow in the country

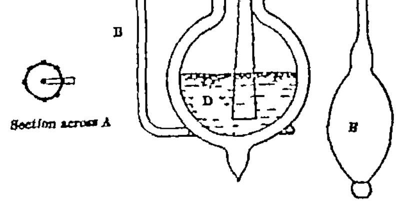
The vacuum flasks in which the liquid air is stored are made of glass and each consists practically of two flasks one inside the other with a vacuum between the two. For use with a Cathcart microtome a support for one of the flasks is a necessary attachment. This attachment is shown in Fig 1.

FIG 1.



A Cathcart microtome is shown on the left. The brass attachment supporting the vacuum flask is seen in the centre of the figure The valvular indiarubber bulb is on the right (From a photograph)

FIG 2



Sectional view A is placed in the sliding cylinder of the microtome. The nozzle is shown on the right of this. B, brass support for, C vacuum flask containing, D, liquid air E, rubber bulb.

The *inner sliding* cylinder of the microtome also requires some modification. It should be of smaller diameter than is usual in the Cathcart microtome and should be fitted with vertical strips of brass This device is necessary for purposes of partial insulation and also to diminish the risk of the cylinders freezing together. A transverse section of the inner cylinder is shown in the small figure to the left of Fig. 2.

A simple nozzle is fitted into the side of the cylinder and is turned up so as to play on the under surface of the plate. An indiarubber cork with two holes is fitted into the vacuum flask. Through one of these holes (the left in Fig. 2) is a glass tube passing from the vapour above the liquid to a piece of indiarubber tubing attached to the nozzle of the microtome. This indiarubber tubing freezes hard when the microtome is in use and thus forms a further support for the flask. Through the other hole in the cork passes another piece of glass tubing one end of which dips below the surface of the liquid air while the other is attached to the valvular indiarubber bulb. It is necessary for this piece of glass tubing to be expanded at the lower end which dips into the liquid air. The whole apparatus is worked on the same principle as a Junker's chloroform inhaler. By means of the valvular indiarubber bulb ordinary air is blown through the liquid air. The liquid air is vaporised and plays on the under surface of the plate of the microtome. As the atmospheric air passes into the liquid air the moisture condenses from the former on the inner surface of the glass tube which soon becomes blocked with ice unless it be dilated as recommended above and as shown in Fig. 2.

The above apparatus may be seen at work at Mr. Charles Baker's, 244, High Holborn, London, W.C., and is sold by him for 30*s* The present form of Cathcart's microtome as modified for use with liquid air is sold for 15*s*. Liquid air is to be obtained for 2*d*. per gallon from the Liquid Air Power and Automobile Co, Limited, 29A, Gillingham-street, Pimlico, London, S.W

In conclusion, I ought to say that I can personally lay no claim to any originality in connexion with the above. The idea of using liquid air for freezing in the laboratory is due to Dr T. B. Hyslop, superintendent of the Bethlem Royal Hospital, and the mechanical adaptation of Cathcart's microtome for the purpose is due to Mr. Hans Knudsen of the Liquid Air Power and Automobile Co., Limited, to whom I now tender my warmest thanks for his kindly interest and generous assistance.

Bethlem Royal Hospital, S.E.

SOME OF THE SURGICAL ASPECTS OF GLYCOSURIA AND DIABETES.

BY LLEWELLYN C. P. PHILLIPS, F.R.C.S. ENG.,
RESIDENT SURGICAL OFFICER, KASR EL-AINI HOSPITAL, CAIRO, EGYPT,
LATE DEMONSTRATOR OF ANATOMY, ST. BARTHOLOMEW'S HOSPITAL.

(*Concluded from p. 1316*)

CLASS III. (*continued*).

Operations on the Rectum.

EXCISION of the rectum by Kraske's operation has been performed on a man, aged 60 years, for carcinoma; he was very corpulent and his liver was enlarged. At the time of operation there was no sugar in his urine, though there was a history that he had suffered from diabetes and albuminuria five years before and had been under treatment at Karlsbad with the result that the sugar was absent for the two years immediately preceding the operation; there was, however, still a trace of albumin. There was a history of rectal trouble for two years with the passage of blood for one year. After excision the wound was plugged with iodoform dressings. The same evening his urine contained 2·4 per cent. of sugar. The next day he was restless and iodoform poisoning being suspected the dressings were changed, the sugar disappearing meanwhile Three days later it reappeared and iodine was no longer detected in the urine. The next day there was a trace of iodine and 4 per cent. of sugar Four days later he died comatose. The coma may have been uræmic in origin, as opium had been administered every two hours and his kidneys were unsound. Desprès records the removal of hæmorrhoids with the écraseur, the patient recovering. The percentage of sugar was from 0 8 to 1 5

In connexion with these cases must be considered a case recorded by Wallace, of a man, aged 72 years, who underwent excision of the rectum for carcinoma. The wound became very foul after a few days. Simultaneously sugar appeared in his urine and reached 2376 grains in 24 This fell to a trace in a month. The highest recorded was 101° F. Wallace considered this to temporary glycosuria. The patient was lost sight afterwards. (*Vide* Table VII.)

Operations on the Extremities.

A large popliteal aneurysm was excised by Trendelenburg. The patient was a man, aged 64 years. Ether was administered and the operation was done with the aid of Esmarch's bandage; it lasted 60 minutes and there was much bleeding on removal of the bandage. He had much pain on recovery from the anæsthetic. The next day his condition was good. On the third day, however, his temperature rose to 103·2° F. and there was slight ptosis on the right side. Later on the same day he became unconscious. A search for sugar was now made for the first time; 6·7 per cent. was found; a slight fruity odour was observable. That evening his temperature rose to 104 3°; the next morning he died comatose. Post mortem a dilated heart, emphysema, and atheromatous arteries were found.

At St. Bartholomew's Hospital the superficial femoral artery was ligatured for a left popliteal aneurysm by Mr. Howard Marsh. The patient was 34 years of age and he had contracted syphilis seven years previously. Sugar was found in his urine for the first time on the day of operation (? before or after the operation). 13 days later sugar was still present. He was discharged a month later surgically well; no mention of diet is made. 14 months later he was admitted under the care of Sir Lauder Brunton with well-marked diabetes (the urine was of specific gravity 1040, the amount was six pints, and it contained 13·8 per cent. of sugar; the total amount present per diem before death was 7262 grains). He died comatose. This was probably a case of diabetes throughout, though Fort's case must be remembered of diabetes the result of an anæsthetic. (St. Bartholomew's Hospital Male Surgical Register, 1896, vol. iv., No. 1696.)

In 1900 Mr. H. T. Butlin amputated the right hand of an engine-driver for epithelioma. He was 45 years of age and was a big corpulent man. On admission his hand was swollen on the inner side and the skin was red, smooth, and painful. His temperature was 97·6° F. and his urine was of specific gravity 1028 and contained 5 per cent. of sugar. The swelling was explored under an anæsthetic and a sinus was found; a piece was removed for microscopical examination. This proving to be epithelioma an amputation was performed through the wrist. Gas and ether were administered on each occasion. All carbohydrates were withheld from his diet. He was quite free from pain the next few days but his temperature gradually rising to 100° on the fourth day the wound was dressed and sloughing of the flaps was discovered. The sloughs separated gradually and on his discharge the wound had practically healed. The following table shows the state of the urine:—

Date.	Amount		Specific gravity.	Percentage of sugar.	Total amount of sugar.	
	in ounces.	in cubic centimetres.			Grains.	Grammes.
June 5th.	—	—	1028	2·0	—	—
„ 6th.	60	1703	1030	5·0	1311·8	85·18 (Operation.)
„ 12th	43	1221	—	8·3	1563 6	101·53 (Operation.)
„ 14th.	75	2129	1032	5·0	—	—
„ 20th	58	1641	—	4·0	1011·0	65·65 (Slough.)
„ 21st	56	1590	1030	4·5	1101·8	71·55
„ 26th	60	1703	1030	4·3	1138·6	73·94
„ 28th.	66	1874	1027	2·5	716·1	46·50

On July 4th, 5th, and 9th only traces of sugar were discovered. The ferric chloride reaction was never present. The percentage of sugar in this case was high and did not materially diminish until the sixteenth day in spite of diet; it eventually became a mere trace. The euphoria during the period of sloughing is noteworthy. He was readmitted in

February and in March, 1901, for removal of enlarged epitrochlear and axillary glands. On the second occasion there was about 1 per cent. of sugar present; the ferric chloride reaction was absent. There was, moreover, no acetone as shown by Legal's test. These two operations were quite successful. (St. Bartholomew's Hospital Male Surgical Register, 1900, vol. iv., No 1479; and 1901, vol. iv.) (Personally observed.)

Three primary amputations on diabetics have been performed with two deaths. Verneuil amputated the foot of a man, aged 52 years, by Roux's method for a crush received the evening before from a wagon wheel. The patient had recovered from the shock of the accident and was willing and ready for the amputation. Hæmorrhage was troublesome during the operation; 24 hours later stupor appeared; chronic diabetes was now discovered to be present (with 3·8 per cent. sugar in his urine) and he died comatose. The stump was quite healthy. This case is quoted by Becker as an example of *coma precipitated by an anæsthetic.*

In St. Bartholomew's Hospital a primary amputation through the upper third of the leg was performed on a woman, aged 60 years, for a compound fracture in the middle third. On the third day the flaps were gangrenous. A charcoal poultice was applied and sugar and albumin were found in her urine. She died on the ninth day. Post mortem a line of demarcation was present; the arteries were very atheromatous. In the third case the inner four digits of the foot were removed by Hache for

TABLE VII.—OPERATIONS ON THE RECTUM.

No.	Sex and age.	Reference.	Disease.	Operation.	Result.	General treatment.	Remarks.
1	—	Desprès.	Hæmorrhoids.	Removal by écraseur.	Recovery.	—	Sugar in the urine from 0·3 to 1·5 per cent.
2	Male; 60 years.	Hoffa	Carcinoma recti.	Kraske's operation.	Plugged with iodoform dressings. Coma. Death.	—	Sugar absent for two years (had suffered from diabetes for five years). The urine contained albumin. Signs of iodoform poisoning. Re-appearance of the sugar after operation. Coma; ? due to uræmia, as much morphia was given after the operation and the kidneys were unhealthy.
3	Male; 72 years.	Wallace	Carcinoma recti.	Excision	Recovery	—	The wound became sloughy a few days after the operation. The urine now contained 2378 grammes of sugar in the 24 hours which fell to a trace in a month. Highest temperature 101° F. ? Diabetes. ? Glycosuria due to sepsis.

TABLE VIII.—OPERATIONS ON THE EXTREMITIES.

No.	Sex and age.	Reference.	Disease.	Operation	Result.	General treatment.	Remarks.
1	Male; 64 years.	Becker (Trendelenburg's case)	Popliteal aneurysm.	Excision.	On the fourth day coma. Death.	—	Ether was the anæsthetic. On the appearance of the symptoms of coma 6·7 per cent. of sugar was discovered.
2	Male, 34 years	Marsh (St. Bartholomew's *Hospital* Surgical Register, vol. iv, 1890)	"	Ligature of the superficial *femoral*	Recovery.	—	Sugar was discovered on the day of the operation (*? before*). 14 *months* later the patient was re-admitted to the hospital and he died from diabetic coma.
3 a.	Male; 45 years.	Butlin (St. Bartholomew's Hospital Surgical Register, vol. iv, 1900, 1901)	Epithelioma of the hand Ulcerated.	Amputation at the wrist.	Sloughing of the flaps (painless) Recovery.	General treatment adopted.	The sugar varied from 5·3 per cent. to *nil*. A stout patient. No ferric chloride reaction.
b	—	—	Enlarged gland at the elbow. 1901.	Excised.	Recovery.	—	A trace of sugar. No ferric chloride reaction.
c.	—	—	Enlarged axillary glands.	"	"	-	About 1 per cent. of sugar. No ferric chloride reaction.
4	Male; 52 years.	Verneuil quoted by Becker	Crushed foot.	Amputation of the foot. Roux's method	Much hæmorrhage. Coma. Death.		Chronic diabetes; 3·8 per cent. of sugar. Stump healthy. (?) Coma due to anæsthetic.
5	Female; 60 years.	St Bartholomew's Hospital Surgical Register, vol iv, 1887.	Compound fracture of the middle third of the leg	Primary amputation in the upper third.	Sloughing of the flaps. Death on the ninth day		Sugar and albumin present. Atheromatous arteries. Line of demarcation.
	-	Hache.	Fracture of the four outer metatarsals.	Partial amputation of the foot	Recovery	-	
	-	Reynier (with Dr. Fourrey)	Sarcoma of the size of an orange on the dorsum of the foot near the root of	Removed.	"		

fracture of the metatarsal bones. The operation was quite successful. Reynier has recorded the successful removal of a sarcoma of the size of an orange from the dorsum of the foot. Seven patients have thus been operated upon with three deaths, the actual number of operations performed on these seven patients being nine. The percentage of patients recovering was 57·1 and the percentage of successful operations was 66 6. (*Vide* Table VIII.)

Fractures in Diabetes.

The statement has been made that in diabetics fractures do not unite properly, non-union or delayed union being the rule. The original paper on the subject I have been unable to find and therefore cannot run to earth the data on which it was based. Several cases, however, have been published in support of this view but their number is very small (being five in all). Against this view are three cases treated at St. Bartholomew's Hospital in which the fractures united in quite a normal manner. Two other cases were also admitted during the last 20 years. Both patients, however, died, one after a primary amputation and one from sepsis from an empyema complicating fractured ribs. (In connexion with this it is interesting to note that Naunyn in his monograph on diabetes states that he has never seen an empyema complicating that disease nor has he found any reliable observation by others of such an occurrence. Furthermore, he states (p. 330) that suppurative inflammation of serous membranes is very rare in diabetes.) Legendre also records a normal result in a fracture of the humerus. Rather full details are appended of these cases of fractures as the subject is one of considerable importance.

CASE 1.—A man, aged 51 years, sustained a fracture of seven ribs from the passage of a wheel over his chest. On admission there was extensive surgical emphysema; his urine contained 5 per cent. of sugar. He was much collapsed and suffering great pain and his breathing was very rapid. Six days later he was dieted and put upon codeine. He was discharged 27 days after the accident surgically cured. There was, however, still 3 per cent. of sugar in his urine.

CASE 2—A man, aged 40 years, fractured several ribs by falling on his right side. On admission to St. Bartholomew's Hospital he was much collapsed and there was surgical emphysema over the right lumbar and thoracic regions. On the day of the accident much sugar was discovered in his urine and a history of thirst, excessive appetite, and progressive loss of strength was elicited. On the eighth day a needle was introduced into his right pleural cavity and pus was discovered. A rib was excised, the chest wall being found infiltrated with pus. He died on the sixteenth day after the accident. The amount of urine passed was from 30 to 50 ounces but no quantitative estimation of sugar seems to have been made nor is there any mention of the diet employed.

Both these were severe injuries which might have proved fatal in a healthy subject, yet one patient recovered without there being any noticeable delay.

CASE 3.—A man, aged 58 years, was admitted to St. Bartholomew's Hospital with a sub-trochanteric fracture of the right femur. His urine on admission contained much sugar; its specific gravity was 1038 Sugar persisted for three weeks to reappear again later as a mere trace. He left the hospital from six to seven weeks after the accident with the fracture quite united. No mention is made of any special medical treatment.

CASE 4—A pronounced diabetic, aged 55 years, was admitted with a Pott's fracture. The fracture united well without any delay. He was subsequently transferred to a medical ward for his diabetes.

Legendre records a fracture of the surgical neck of the humerus from direct violence in a woman, aged 60 years, who suffered from intermittent diabetes. Union was complete in four weeks and two months later her arm was as useful as before. During treatment glycosuria was intermittent but there was a large increase in the nitrogenous excretion.

An interesting history is published by Spitzer of a professor, aged 46 years, a very intellectual man, who had been under his care for diabetes since 1895. The total daily amount of sugar was reduced by diet from 12 to 25 grammes to from five to 10 grammes and the daily excretion of ammonia was one gramme and under Acetone and aceto-acetic acid had always been absent. On June 27th, 1899, he was seen and his urine contained 0 8 gramme of ammonia in the 24 hours and 18 grammes of sugar (0 9 per cent.). There was no albumin and no ferric chloride reaction was given. On the 29th about 11 A.M. he fell and fractured his clavicle at the junction of the inner and middle thirds. At 3.30 P.M. he had a sensation of tightness about his chest His urine from the 29th to the 30th measured 5·1 litres, containing 245 grammes of sugar (4·8 per cent.). Sodium bicarbonate was now given by mouth and by rectum (70 grammes in all per diem). He improved until July 3rd, when he became rather restless. His urine was now strongly acid and gave the ferric chloride reaction. He was excreting 2·1 grammes of ammonia despite alkaline treatment. He became steadily worse and died on the 6th comatose. Oxybutyric acid was apparently absent throughout. This case is particularly interesting on account of the coma obviously induced by trauma and on account of the increase in the ammonia and the possibility of giving an unfavourable prognosis.

An account has already been given of the compound fracture for which amputation was unsuccessfully performed. Smith and Durham quote three cases in which the fracture took from four to five months to consolidate and two in which non-union occurred. On the death of one of the latter patients some nine months later from an accident a false joint was found with much provisional callus; nevertheless, the arm was quite useful.

Several cases of transitory glycosuria after fractures have been recorded, the most interesting being Renard's case, where owing to the absence of pain sugar was suspected and found to disappear in a few days. Highly saccharine food failed to cause any return of the glycosuria. The amount also was slight, being only 0 63 per cent.

In connexion with this subject the following remarks of von Noorden are noteworthy: "According to the researches of Toralbo, van Ackeren, and Gerhardt, diabetics often excrete such an excess of phosphoric acid and lime salts over the quantity in the food ingested that they must come from one of the tissues of the body. This can only be from the bones. Gerhardt attributes this to the increased acidity; administration of alkalies diminishes the excretion of lime." Osteomalacia, in which a similar increase in the amount of lime and phosphoric acid excreted occurs, arising in unfavourable conditions of nutrition, &c., sometimes passes over into diabetes under more favourable surroundings (Lymann). Naunyn states that imperfect union may occur even though at the time sugar be not excreted; this he also attributes to hyperacidity. He also refers to the frequent painlessness of fractures in diabetic subjects. Thus, out of 12 cases of fracture in diabetic subjects three of the patients died, one after a primary amputation, one from coma induced by the shock of the accident, and one from pyopneumothorax the result of fractured ribs. In five cases union was delayed or was non-existent. In the remaining four union resulted in a normal manner. The number of cases is small, but when it is considered that the fact that union was not normal led to the publication of five of the cases and that of the other four three were taken from the casebooks of a large hospital (St. Bartholomew's) from the years 1884 to 1900, and that the result was quite good as regards union, considerable doubt must be thrown on the former statement that non-union was very common. But taking van Noorden's observations *re* the lime salts into account it would certainly be advisable to administer lime salts, preferably the carbonate, on account of the liability to the occurrence of acids in excess, to every diabetic who should be so unlucky as to sustain a fracture. (*Vide* Table IX.)

CLASS IV.

This class includes all those cases in which a septic element is already present at the time of observation. It includes, therefore, gangrene, abscesses, carbuncle, middle-ear disease, &c. A short reference will be made to gangrene and the subject of middle-ear disease will be more fully considered.

Gangrene.

Gangrene is, as has been stated already, rarely the direct result of diabetes, occurring only indirectly as the result of arterial sclerosis or nerve degeneration. The term "diabetic gangrene" is usually applied to gangrene of the lower extremities. A vast amount of literature has accumulated around the subject and the subject is further complicated by the fact that ordinary senile gangrene may be complicated by glycosuria. The best paper on the subject is that of Gussenbauer, with whom my own researches agree. He advocates diet and general treatment in the first place. The condition of the arteries should be carefully investigated on both sides. If the pulse be distinctly present in the anterior

TABLE IX.—FRACTURES IN DIABETICS.

No.	Sex and age.	Reference.	Injury.	Operation.	Result.	General treatment.	Remarks.
1	Male; 51 years.	St. Bartholomew's Hospital Surgical Register, 1899, No. 1492.	Fracture of seven ribs from wagon wheel	—	Recovery without delay.	Adopted on the sixth day after the accident. Diet and codeine.	Much surgical emphysema. Urine: 5 per cent. of sugar; on discharge on the twenty-seventh day 3 per cent.
2	Male; 40 years.	Ibid., vol. iv., 1890.	Fracture of several ribs from a fall. Empyema. (The chest wall infiltrated)	Excision of a portion of a rib on the eighth day.	Death on the sixteenth day.	Not mentioned.	Diabetic history. The amount of sugar not recorded. Much surgical emphysema.
3	Male; 58 years.	Ibid., vol. iii., 1891.	Sub-trochanteric fracture of the femur (right).	—	Recovery (left the hospital in from six to seven weeks).	”	Urine: specific gravity 1058; much sugar. After three weeks the sugar had nearly disappeared.
4	Male; 55 years.	St. Bartholomew's Hospital, Matthew Ward book, 1890.	Pott's fracture.	—	Recovery. No delay.	—	A pronounced diabetic. Subsequently transferred to a medical ward.
5	Female; 60 years.	Legendre.	Fracture of the surgical neck of the humerus.	—	Recovery. Union complete in four weeks.	—	Intermittent diabetes. Much increase in excretion of urea.
6	Male, 35 years.	Verneuil (Bulletin de l'Academie de Medecine, 1889).	Compound fracture of the left femur.	—	Sloughing and ulceration. Union nearly complete in four months.	—	Diabetes for four years. From two to three litres of urine; much sugar. Delayed union (but the fracture was compound).
7	Male; 67 years.	”	Fracture of the neck of the humerus.	—	Much callus. Three months later, on death occurring from an accident, pseudarthrosis was discovered.	Refused.	Diabetes for two years. 10 litres of urine; much sugar. Non union.
8	Male; 54 years.	”	Fracture of the radius and ulna.	—	Non-union; still present nine months later.	Adopted.	Reduction of the sugar present from 7·96 per cent. to nil. For four years symptoms of diabetes.
9	Male.	Berger.	Fracture of the lower third of the leg.	—	Union complete in 14 weeks.	”	Diabetes for years. Sugar from 7·5 per cent. to 4·8 per cent.; reduced by treatment to 1·7 per cent.
10	—	Lésty (Smith and Durham).	Fracture of the leg.	—	United in five months.	—	Diabetes.
11	Male; 46 years.	Spitzer.	Fracture of the clavicle, June 29th, 1899.	—	Death on July 6th from coma.	Adopted	The patient had been under medical treatment for four years for diabetes. The amount of sugar per diem rose from 18 grammes to 245 grammes (from 0·9 to 4·8 per cent.) and the amount of ammonia from 0·9 gramme to 2·1 grammes per diem in spite of sodium bicarbonate.

and posterior tibials and in the dorsalis pedis local removal of the diseased parts will suffice. If, however, the pulse be not perceptible there, but be well marked in the popliteal, amputation below the knee may be performed, provided that the gangrene has not spread beyond the dorsum of the foot and that the leg is free from phlebitis and lymphangitis. If, however, these conditions be not fulfilled or the popliteal pulse be not felt, then amputation must be performed through the thigh. If gangrene has spread beyond the dorsum of the foot, or if the urine contains acetone or aceto-acetic acid, or if stupor or hiccough is present, the prognosis is necessarily bad. He illustrates his paper with nine cases, of which the following two are the most instructive. A man, aged 56 years, who had suffered from diabetes for some years, became the subject of gangrene of the right foot, the dorsum and sole being affected. Lymphangitis was present above the internal malleolus. He was dieted. Gritti's amputation was performed with success. Two years later, general treatment having been in abeyance in the meantime, the left great toe became gangrenous. The dorsalis pedis distinctly pulsating a local amputation was performed, the patient recovering perfectly. In the other case, though the brachials were rigid and the posterior tibial pulse could not be felt, the dorsalis pedis and popliteal pulsated distinctly. Local removal was successful after dieting and local antiseptic measures. The urine contained 4·8 per cent. of sugar. As a local disinfectant he employed aluminium acetate. He does not refer to the state of the reflexes, though these should certainly be considered. It will also be observed that he does not limit himself to the simplest operations but employs such methods as Gritti's. During the years 1884–1899 the following were the numbers of cases treated at St. Bartholomew's Hospital: unoperated, 11 cases, all resulting fatally; and amputated, eight cases with six deaths. Of the latter in six cases an amputation below the knee was performed; one patient recovered after sloughing of the flaps, the wound not completely healing for many months. Among the fatal cases sloughing of the flaps occurred in four; in the fifth the patient died on the sixth day demented, the wound being united by primary union. In this case there was no tibial pulsation and the amputation was below the knee. In the remaining two an amputation through the thigh was performed. One recovered after slight suppuration during the course of which he became very restless and almost comatose. The other, a woman, aged 79 years, died, probably from sepsis as the wound did not run an aseptic course; the gangrene in this instance was moist. The arteries were healthy but the nerves were degenerate. If in doubt an amputation should be performed above the knee rather than below. A few cases of gangrene of the upper extremities have been recorded. Grossman's paper based on some 224 cases of gangrene in diabetes I have been unable to consult save in a review. He also emphasises the importance of arterio-sclerosis and nerve changes. He further states that a slight amount of sugar in the tissues is favourable to the growth of pyogenic cocci and their symbiosis with other bacilli.

The following case of gangrene which was under the care of Mr. W. J. Walsham is of interest, as the amount of ammonia was estimated, and being excessive sodium bicarbonate was administered with success. The patient eventually died and though before death he was unconscious, yet death cannot be considered to have been due to diabetic coma as the temperature was raised and bacteriological examination of the blood showed streptococcus poisoning. Death was therefore due to sepsis.

The patient, a male, aged 67 years, was admitted on April 17th, 1901, with gangrene of the second toe on the left foot; this resulted from some damage earlier in the winter. On admission he was well nourished and his temperature was normal. There was sugar in the urine but the amount at the time was not estimated. The urine contained 1·5 grammes of ammonia in the 24 hours. He was then placed on sodium bicarbonate in 30-grain doses thrice daily which were increased later to 90-grain doses every four hours. This reduced the ammonia to 0·25 gramme. The sodium bicarbonate, however, made him vomit. He was at the same time dieted and was placed on codeine. After the above preliminary treatment the leg was amputated through the lower third by lateral flaps (the patient not consenting to an operation higher). The arteries were diseased; a microscopical section of the posterior tibial showed a channel thrombus. On the third day after a rigor gangrene was discovered to have spread to the flaps. (The original operation was performed on April 30th.) After dressing the temperature fell for a few days but it rose again, and as he got steadily worse a further amputation was performed through the lower third of the thigh by antero-posterior flaps, but owing to his general septic condition at the time he was not much improved and finally he became unconscious and died late on May 16th. (The second operation had been performed on the 14th.) His temperature just before death was 102° F., having been the day before from 103° to 104°.

Necropsy.—The arteries about the base of the brain were very atheromatous. The lungs were emphysematous and very œdematous. The heart was hypertrophied (18 ounces). The liver was slightly enlarged and there was an empyema of the gall-bladder; the gall-bladder was also adherent to the duodenum by recent lymph. The spleen was diffluent. The kidneys were enlarged (18 ounces). The pancreas was normal to the naked eye. The tissues of the stump were sloughing but there was no osteomyelitis of the femur. The femoral artery was rather atheromatous.

Bacteriological examination.—In the heart's blood there were streptococci, with contaminations. A subculture yielded pure streptococci.

Microscopical examination.—The pancreas showed no trace of degeneration; on the other hand, its cells seemed to be large and active. The kidneys, save for some round-celled infiltration and cloudy swelling such as would be accounted for by the temperature, were normal in appearance. The amount of urine varied between two pints and four and a half-pints. The amount of sugar was between 0·4 and 1·64 per cent. The largest amount was on May 9th when 736 grains were excreted in the 24 hours. The temperature was normal on this day. The average total amount was about 300 grains. (Personally observed.)

Diabetes and Otitis Media.

Much has been written by foreign surgeons on the relation between otitis media and diabetes. Some consider that there is a special diabetic form in which mastoid symptoms predominate; some even consider that the mastoid is primarily affected. Kuhn, Raynaud, and Wolf are the chief exponents of this idea. Friedrich's views are similar; he considers the reason of the early, if not primary, mastoid disease to be the existence of arterio-sclerosis. Eulenstein has collected from the published papers a large number of cases which with his own amount to 50 in all; 45 of these were acute cases. Of these 50 cases 17 patients developed extensive mastoid disease, 11 developed slight mastoid disease, and 22 had no mastoid complications. Therefore, in 56 per cent. mastoid complications occurred. Of the acute cases the time of occurrence of the mastoiditis is mentioned in 12, in eight of which it occurred within a month of the onset of otitis media, in one case appearing as early as on the sixth day. Eulenstein states, however, that he has seen mastoiditis as precocious in non-diabetic cases. When it is remembered how in diabetics sepsis frequently runs riot it is not surprising that extensive suppuration and necrosis take place, since the mastoid process furnishes a good nidus for the organisms to develop. In many instances (Sheppard's case in particular) diabetes was not discovered until extensive cellulitis occurred in the neck, spreading down from the tip of the mastoid process and often reaching the clavicle. In the section on the influence of diet on the course of wounds a clinical history of such an occurrence was given where, on the discovery of 3·7 per cent. of sugar, rigid diet was adopted, the patient recovering completely. Sheppard's patient also recovered.

Pain is a prominent symptom and occurs early. In one of Friedrich's cases there was tenderness over the mastoid on third day of the attack in addition to severe pain over the side of the head.

The affection may be thus summed up. Otitis media is common in diabetics, infection spreading up from the pharynx which is often in a state of chronic catarrh. Its onset is sudden; the pain is of great intensity and persistence, even though there be free discharge through the external meatus; the discharge is often bloody; and there is a great tendency to mastoiditis and necrosis (Eulenstein). In many instances extensive cellulitis of the neck succeeds operation, but in others the disease has run quite a normal course. All are agreed that if an operation be required it should be performed in spite of the presence of sugar, general treatment being also adopted. Particular attention should be paid to Gerhardt's reaction and to the amount of ammonia excreted. Thus Lannois operated on a man whose urine measured three litres per diem with a percentage of sugar of 9·8, but the amount of ammonia was low. He recovered from the operation in spite of gangrene of the skin (he died suddenly two months later, the mastoid having quite recovered). In the case of a man, aged 42 years, a drinker, whose urine contained 5 per cent. of sugar and albumin, Friedrich merely opened an abscess over the mastoid under the ether spray, the abscess healing completely. He thinks that if the percentage of sugar be high and uninfluenced by diet, or if the heart, the lungs, or the kidneys be unsound, the prognosis is bad and a simple operation under a local anæsthetic should be performed.

Other Septic Affections.

Spencer records an interesting case of cellulitis starting in the bursa olecrani for which he performed an amputation, the patient recovering, although the operation was performed through indurated tissues and although at the time of the operation he was in a semi-comatose condition. The following case recorded by Naunyn is of interest from the fact that it bears out the observations of Nicolas that glucose favours the pyogenic properties of many organisms whilst it diminishes their virulence. A man, aged 62 years, came under observation, after undergoing several rigors, with a large abscess in the left thoracic region. Although at the time of the rigor the right half of his prostate was enlarged it was scarcely painful. The urine contained 11 per cent. of sugar but no other abnormal substances were found in it. A large abscess formed in the prostate and spread up behind the symphysis pubis; the thoracic abscess also spread widely; nevertheless, both healed up completely after incision. Thus very extensive suppuration is not necessarily fatal in diabetes. Other septic affections, such as carbuncle, will not be considered.

GENERAL CONCLUSIONS.

These conclusions are based on the cases in Group III. and all the doubtful cases of temporary glycosuria, such as one of Tuffier's tongue cases and Giles's fibroid case, have been omitted. It will be seen on examination of the tables that most of the principal major operations of surgery have been performed with a large amount of success. In all 92 operations have been performed on 83 patients, of whom 23 died, giving a percentage of patients recovering of 72·28 and of successful operations a percentage of 75. This at first seems to indicate a high mortality, but when it is considered that in three cases death seemed to be inevitable within a few days if an operation was not performed the mortality is not unduly high. (These three cases include two strangulated herniæ, in one of which coma was already appearing and in the other gangrene of the gut was present, and an inguinal colotomy for complete obstruction, an operation at all times extremely grave when obstruction is present.) Further, in 11 cases the operation was performed for malignant disease, and since the latter is more likely to be fatal within a shorter period than diabetes in an elderly subject much must be risked to gain much. The same cannot be said of the parotid tumours, as their nature is not indicated, but one was undertaken on an at that time unknown diabetic and was a very difficult operation. The dermoid tumour of the ovary was a very difficult operation owing to the extensive adhesions. The patient who underwent Kraske's excision of the rectum also had unsound kidneys and probably died from uræmic coma induced by the use of much opium. The excision of a popliteal aneurysm was also on an unsuspected diabetic.

The operations of expediency were singularly successful. These include five radical cures of hernia, six plastic operations on the female generative organs, and one operation for piles. A case of vaginal hysterectomy for procidentia, however, was fatal. The actual cause of death was coma in 11 cases and sepsis in seven; of the others pneumonia and shock figure, whilst in three the cause is doubtful. (Coma and sepsis will be considered separately later.) Of these 83 patients 35 were males, of whom 24 recovered, and 42 were females, of whom 32 recovered, the percentage being of males 68·5 and of females 76·1; of the remaining six of unstated sex five recovered. This predominance of females is probably due to the fact that the disease was not so acute. Of 49 patients over the age of 45 years 19 died, whilst of nine under that age only one died. Two contrary factors are at work here, one being the more chronic nature of diabetes in advanced life but accompanied by the great probability of arterial and nerve-degeneration. The details are too meagre to draw accurate conclusions of the influence of nerve-degeneration on healing, the only ones available being Reynier's. He has drawn up some tables of cases with and cases without knee-jerks, of which, however, the only comparable cases are the septic ones. Of these, of 13 septic cases in which they were absent all died, whilst of 13 in which they were present only two died. But the cases in the first group seem to have been more severe.

As to the condition of the urine, the percentage of sugar is no criterion as fatal results have followed from coma when no sugar had been present there for some time previously. The highest percentage in fatal cases was eight and in non-fatal cases was 11·5. A more instructive figure might be obtained if the total sugar excreted per diem were considered, but as this is in so many recorded cases impossible to ascertain it will not be further considered. Albuminuria is a serious complication; the three patients in whom it was present all died. The presence of abnormal substances, such as acetone or aceto-acetic and oxybutyric acids, and with them an increase in the amount of ammonia excreted, is of the utmost significance, and if irreducible of unfavourable prognosis. This will be considered in detail in the section on coma. In none of the cases in Group III, save in a fracture case, was the amount of ammonia excreted stated, and here its persistance indicated an unfavourable prognosis which was fully borne out by the fatal termination. In one or two of the otitic cases it has been recorded, and in the case of gangrene under Mr. Walsham's care an increase in the amount was discovered, but this responded to treatment, the patient, however, ultimately dying, but not from coma. Alcoholism is considered by Verneuil to exert an unfavourable influence. In many of the cases the patients were full-bodied, constituting the condition called "diabète gras." Many of the older writers consider that diabetes exerts a baneful influence on the healing of wounds, but this apart from sepsis does not necessarily follow, it must be remembered, however, that a wound may slough or suppurate without any pain or even much rise of temperature. This euphoria is rather a noticeable feature in such cases (*vide* the amputation of the hand and the vaginal extirpation of the uterus) But of wounds of the anterior abdominal wall, as for operations for radical cure of umbilical herniæ, ovariotomies, &c, out of 15 in seven union was not good, disunion even occurring in three, no union in one, and in three its progress was described as being slow Preliminary treatment was adopted in 34 cases, in six of which the patients died, two from sepsis and two from coma. In 11 cases there was no preliminary treatment. Of these four patients died, two from sepsis and two from coma. The percentage of recoveries of the dieted is therefore 82·3 and of the undieted 63·63. Though the number of non-dieted cases is small yet the difference in result is 18·66 per cent. Of those in whom the preliminary treatment was doubtful 13 out of 39 died, yielding a percentage of recovery of 66·66. In none was the sodium carbonate treatment adopted. The effect of diet on pre existing sepsis is strikingly shown in the following case reported by Davidsohn.

A man, aged 49 years, was admitted in July, 1894, suffering from suppurative otitis media. This dated from a chill on May 6th, discharge appearing on the 9th. No fresh symptoms were noted until pain appeared behind the ear on July 3rd, followed by a rigor on the 6th. On the 9th there was obvious mastoid suppuration. The mastoid was explored on the same day by Schwabach. The bone was diseased and was scraped and the wound was packed with gauze. The progress of the wound was favourable until the 26th, when brawniness due to cellulitis of the neck occurred This had spread down to the clavicle by the 30th in spite of free incisions. Counter-incisions were freely made under an anæsthetic. Slight improvement resulted, but two days later the discharge was very offensive and contained sloughs A history of diabetes reaching back to February was now elicited, the urine containing 3·7 per cent. of sugar Under rigid diet in eight days the percentage fell to 1 and in nine days it disappeared, the wound at the same time healing rapidly, so that by the end of August it was completely healed The perforation in the membrane healed and the patient gained weight.

Many other similar cases might be cited (*vide* Table III on operations on the breast).

Diabetes and Sepsis.

Some foreign surgeons have emphatically stated that if after an operation the wound for no apparent cause becomes septic or sloughs the urine should be examined for sugar. This sometimes will be found present although absent immediately before, since in some cases diabetes is latent, sugar reappearing after the disturbance of functions caused by the anæsthetic or by the mental effects of the operation. This is comparable with the well-known increase in the amount of the sugar excreted, which often occurs under such circumstances. Kraske, Fischer, Bujwid, Müller, von Noorden, and others have demonstrated the presence of staphylococcus aureus, staphylococcus albus, and other suppurative micro-organisms in the septic processes that occur. Occasionally moulds have been found associated with the abscess formation in diabetes (Auché and Dantec) Bujwid performed a series of experiments and showed, (1) that sugar was not produced by the growth of staphylococcus aureus; (2) that its growth in a culture containing sugar was less luxuriant than in a sugarless though otherwise similar medium and further that its growth was colourless; (3) that that amount of staphylococci which when suspended in an indifferent though sugarless fluid did not produce suppuration when suspended in a similar though sugar-containing fluid did produce it, (4) that if the injection of a subminimal amount of staphylococci into an animal were followed by the injection of normal saline fluid no suppuration ensued, whereas the injection of a sterile solution of sugar was attended by suppuration, and (5) that if the sugar solution were withheld until the staphylococci disappeared from the blood no suppuration resulted. In one animal gangrene of the skin ensued on the introduction of a sugar-containing fluid

These experiments have been repeated by Nicholas and Karlinski with similar results Nicholas showed, however, that the actual sequelæ differed slightly with the seat of injection, a subminimal dose of staphylococci producing a slightly different result according as to whether it was injected into the blood stream or into the cellular tissue Further, such a dose of cocci followed by sterilised water produced suppuration almost as readily as did a solution of sugar, showing that it was not so much the sugar as the damage to the tissues produced by it In addition, a dose of staphylococci sufficient to kill an animal in a few days, if followed by a solution of sugar, either did not kill it at all or only after a much longer period, and that a large abscess made its appearance instead of a small one or septicæmia. Ferrero has established similar facts for staphylococcus albus Thus sugar diminishes the virulence of micro-organisms but increases their pus-producing properties.

In addition to the lowered vitality produced by the circulation of an abnormal amount of sugar the presence of arterio-sclerosis and nerve degeneration must be taken into account, for the diabetics that usually seek surgical aid are middle-aged or at least suffering from a chronic form of the disease; for many are stout full-blooded individuals (*diabète gras*). With reference to nerve degeneration, it is well known that after severance of a nerve there is a greater tendency to trophic lesions. Herman and Kasparek have performed a series of experiments with the pyogenic organisms and have shown that after the division of the sciatic nerve on injection of the organisms suppuration was liable to follow on the injured side in the marrow and joints. Thus there is abundant reason for the occurrence of suppuration in diabetics. The sugar directly lowers the vitality of the tissues and by inducing chronic vascular and nerve changes also adversely affects the body. It must be remembered in this connexion that sepsis sometimes produces temporary glycosuria, but even here there is a difficulty, for the patient may be suffering from intermittent diabetes, and the shock of the operation may cause it to reappear.

Coma.

It is well known that in diabetic subjects the most trivial incident or accident may be followed by coma, whilst, on the contrary, at times even the most severe injury may be sustained without any untoward result. It is therefore advisable to study in detail the pathology of diabetic coma. In diabetic coma the urine contains one or more abnormal substances the principal of which are acetone, and aceto-acetic and oxybutyric acids. Dreschfeld has shown that considerable amounts of acetone and aceto-acetic acid can be administered to man or animals by mouth without any bad consequences and that little of them can be recovered from the urine. Moreover, acetone can be subcutaneously injected without danger provided that the amount be small and that elimination be not hindered, but if these conditions be not observed the animal passes into a state closely resembling diabetic coma. These bodies have also been found in the urine of patients who have died comatose after such diseases as malignant disease of the liver. These bodies also cause albuminuria—a condition alleged by Stokvis to be an accompaniment of diabetic coma. Huchard, Kirstein, Coranda, Hallevorden, and others consider that coma is due to acid poisoning. Stadelmann and Minkowski have discovered an acid in the urine of certain diabetics identical in composition with oxybutyric acid but lævo-rotatory, the artificial acid being optically inactive; this they therefore call "oxybutyric acid." The actual mode of operation of these acids seems to be that they become neutralised by the sodium carbonate present in the blood and that if they are present in excess there is considerable risk that the alkalinity of the blood may be so reduced that it is unable to carry on its functions in an efficient manner. That this is so in animals is proved by the fact that if sodium carbonate be injected acid poisoning does not occur. Minkowski found in a comatose patient only 19·5 volumes per cent. of carbonic acid instead of the normal 35 volumes. This fact shows that its alkalinity was reduced. Diabetic blood is still, however, toxic, though to a less degree, after its alkalinity has been restored

There seems, however, to be a safety-valve arrangement, for with an increase of indestructible acids in the urine there is a concomitant increase in the amount of ammonia excreted; this may be as much as from four to six grammes, or even more, per diem instead of the normal 0·7 to 0·9 gramme. In febrile conditions it also rises. Therefore, by destruction of the proteids a certain amount of ammonia instead of urea is set free whereby the fixed alkalies of the blood are protected. Naunyn sums up the matter thus. In severe diabetes, especially in young patients, the acids are excreted combined with fixed alkalies; if the acidosis be excessive they are also excreted in combination with ammonia obtained by the destruction of proteid (ammonia taking the place, in part, of urea, the amount of ammonia excreted being an index to the danger of death from coma). If more than three grammes of ammonia be excreted per diem there is great risk of coma and if it exceeds four grammes, in his experience, coma is inevitable sooner or later. Becker has brought forward the hypothesis that coma, as a post-operative complication, is frequently induced by the anæsthetic. He found that acetone, as indicated by the nitro-prusside test, was present in 125 out of 188 patients after the administration of a general anæsthetic (66 per cent.). Abram repeated these observations and found it in 16 out of 25 (64 per cent.), and that on distillation it could be detected in all. It remained in the urine for from five to eight days, but there was no relation between its duration and the length of the anæsthesia. After ether Becker found it in 67 per cent. out of 148 cases. After chloroform Abram found it in 75 per cent. (the number of cases was, however, small). In six instances Becker found aceto-acetic acid as well. Kast and Master have found that prolonged chloroform narcosis causes increased proteid destruction with an increase in the amount of acids excreted. These facts indicate that a general anæsthetic is attended, in a diabetic subject, with a risk of the supervention of coma. It must be remembered that every case of coma in a diabetic is not necessarily of diabetic origin; in some it may be the unconsciousness of septic poisoning, in others, as in the fatal excision of the rectum, it may be possibly of uræmic origin. In the cases in Group III. the youngest save one, who was described as "a young woman," was 47 years of age; all the rest were over 50 years, but the majority of diabetics who undergo surgical operations are middle-aged. Coma the result of an anæsthetic usually appears within the first 48 hours. Occasionally the anæsthesia passes direct into it. After a hysterectomy by Landau, a suprapubic cystotomy, and a catheterisation under chloroform the patient in each case died from coma, in all probability the result of the anæsthetic.

Indications against Operation and Rules for the Conduct of Operations.

A thorough examination of the urine must be made in all cases. Not only the amount of sugar is to be ascertained but the presence or absence of acetone or acid bodies; the ferric chloride reaction and Legal's test are to be employed in every instance. The presence of oxybutyric acid is not easy to demonstrate or to estimate save by the polarimeter. The total amount of ammonia must always be estimated. 1. No operation save of the extremest urgency is to be performed if there is over one gramme of ammonia excreted in the 24 hours until this has been reduced to the normal amount. 2. An operation should be postponed if there be aceto-acetic acid in the urine, though the ammonia be not markedly increased. 3. Much albumin in the urine is a bar to operation. 4. If serious disease of other organs such as the liver be present an operation should be avoided. 5. Rapid wasting in a stout diabetic not obviously dependent on the surgical lesion demanding treatment should be a reason for postponing an operation until the general condition be improved. An operation should be performed: (1) for malignant disease, if apart from diabetes such would be urged; (2) in the case of large abdominal tumours, especially in females; (3) in diabetics in good health without extensive arterial or nerve-degeneration cosmetic operations may be performed, especially in females; and (4) an emergency operation is to be undertaken even in the most unfavourable circumstances, but a very guarded prognosis is to be given. Save in the last category, if any of the indications against operation be present the operation should be postponed until they are ameliorated.

Preliminary treatment and method of operation.—In all cases in which delay does not mean loss to the patient a careful diet is to be adopted; further drug treatment, such as codeine or morphia, may be adopted. If ammonia be present in excess sodium bicarbonate is to be administered daily until the percentage becomes normal; the actual amount required may be as much as from 30 to 40 grammes per diem. Should it make the patient vomit it may be given per rectum. By this preliminary treatment the risk of sepsis and coma is lessened. Such operations as can be conveniently carried out under a local anæsthetic should be performed by its aid. Laisney operated on 102 cases of cataract, with 99 successes (Legendre), and Glasscott operated on 30 cataracts under cocaine without mishap (Dreschfeld). If a general anæsthetic be employed ether may possibly be safer than chloroform, but in any case sodium carbonate is to be administered for a few days before and after. If the increased vulnerability of the tissues be considered an aseptic rather than an antiseptic operation is the ideal undertaking. All strong antiseptics are to be kept from the wound. Further, the patient is not to be considered cured until the wound is completely healed. Hæmorrhage under modern methods of operation is not to be feared. In operations upon the urogenital organs where asepsis is difficult to maintain an internal antiseptic such as urotropine should be administered.

SOME NOTES FROM AN INQUIRY INTO THE ACTION OF DINITRO-BENZENE UPON THE URINE OF MAN,

AND EXPERIMENTS PROVING THE INNOCUOUSNESS OF DINITRO-TOLUENE UPON ANIMALS.

BY R. PROSSER WHITE, M.D. EDIN., M.R.C.S. ENG.,
HONORARY MEDICAL OFFICER TO THE ROYAL ALBERT EDWARD INFIRMARY, WIGAN;

JOHN HAY, M.D. VICT., M.R.C.S. ENG., &C.,
MEDICAL TUTOR AND REGISTRAR AT THE ROYAL INFIRMARY, LIVERPOOL, AND ASSISTANT PHYSICIAN TO THE STANLEY HOSPITAL, LIVERPOOL;

AND

W. J. ORSMAN, F.C.S., F.I.C.,
LECTURER ON CHEMISTRY AT THE WIGAN TECHNICAL COLLEGE AND ANALYST TO THE COUNTY BOROUGHS OF WIGAN AND SOUTHPORT.

IN this inquiry we find that a dose which is immediately fatal or fatal within 24 hours does not exhibit its presence in the urine of man or animals. On the other hand, animals fed upon continuous doses—that is, doses which cause serious and dangerous symptoms or death in a few days—show well-marked pathological features in their urine. These consist of tube casts, brown flakes, and hæmoglobinuria. This latter point has been well worked out by Strassmann and Stocker. In our experiments the dinitro-benzene was administered either hypodermically, or by innunction through the skin to cats. None of the urine of cats so killed showed any perceptible change of colour and in only one which had died from slow chronic poisoning did we find an indication of free dinitro-benzene.

In no fatal case of poisoning amongst the workmen have we ever discovered any evidence of blood corpuscles or hæmoglobin in the urine. In chronic and subacute cases the typical dark tawny colour of urine is always well marked, which is probably due to some pigmentary derivatives, not to free hæmoglobin. No doubt large and long-continued doses given by the mouth to men would produce, as in animals, hæmolysis, broken-up blood-clot in the intestines, and the exudation of blood into the tubules of the kidneys. But we find that neither in the inhalation of dinitro-benzene vapour, its absorption through the skin, nor when given hypodermically to man or animals, are the grosser lesions observed, even in fatal cases. This fact strengthens us in the belief that it is chiefly through absorption by *the skin* that cases of poisoning occur during the industrial manipulation of this substance.

We have tabulated below the results of the analysis of the urine of men who were constantly working with dinitro-benzene. Each case was of an exceedingly mild character. The frequent presence of urobilin has not been recorded previously and points to the powerful hæmolytic action of this poison even when absorbed in very minute doses.

A TABLE SHOWING THE RESULTS OF THE ANALYSIS OF THE URINE OF MEN WHO WERE CONSTANTLY WORKING WITH DINITRO-BENZENE

No.	Specific gravity water = 1000	Appearance.	Colour.	Reaction to litmus.	Urea per cent.	Albumin.	Bile pigments.	Sugar.	Urobilin.	Dinitro-benzol.
1	1029	Clear.	Red brown.	Acid.	2 6	*Nil.*	*Nil.*	*Nil.*	*Nil.*	*Nil.*
2	1030	„	Yellow.	„	—	—	—	Present.	—	„
3	1024	Slight precipitate mucus.	„	„	—	*Nil.*	*Nil.*	*Nil.*	*Nil.*	„
4	1021	„ „	Red brown.	„	—	„	„	„	„	„
5	1025	Heavy red precipitate.	„ „	„	—	„	„	„	Present.	Trace.
6	1027	Clear.	„ „	„	3·3	„	„	„	*Nil.*	Faint trace.
7	1026	Thick white precipitate.	Pale yellow.	„	2 9	„	„	„	„	„ „
8	1026	Red deposit.	Red brown,	„	3 1	„	„	„	Present.	*Nil.*
9	1022	„ „	„ „	„	3·0	„	„	„	„	„
10	1022	Clear.	Yellow.	„	2 8	„	„	„	*Nil.*	„
11	1027	Red deposit.	Red-brown	„	3·1	Trace.	Trace.	„	Present.	„
12	1025	„ „	„ „	„	2·9	*Nil.*	*Nil.*	„	„	„
13	1024	„ „	„ „	„	2 3	„	„	„	„	„

It will be noticed in the above table that all the samples are acid, many being strongly so. Nearly all are dark-brown in colour and generally precipitate out a red deposit, principally urates. In most of these urobilin is present and can be easily recognised by the following test. 100 cubic centimetres of the urine are acidified with 10 drops of strong hydrochloric acid and are then shaken with 20 cubic centimetres of chloroform. The chloroform which falls to the bottom is separated by means of a separating funnel and filtered into a test-tube. Four cubic centimetres of a solution of one gramme of crystallised acetate of zinc dissolved in a litre of 95 per cent. alcohol is then poured gently down the side of the test-tube and at the junction where the liquids meet a green fluorescent ring characteristic of urobilin will appear, and on shaking the solution will become fluorescent, being green by transmitted light and rose-coloured by reflected light. This pigment can also be detected by means of the spectroscope.

No experimental evidence has yet proved that reduction takes place in the body in case of the nitro compounds of benzene to aniline or phenylene-diamine. In several samples of urine tested both nitrates and nitrites were present, so that in the case of phenylene-diamine being present the pigment Bismarck brown would be formed and would give the urine a brown tint. The samples of urine were tested for free dinitro benzene by the following method. The urine is treated with zinc and hydrochloric acid for some hours. Any dinitro-benzene that may be present is reduced by the nascent hydrogen into phenylene-diamine. The urine is then alkalised with caustic soda and well shaken up with ether. The ether is then separated, filtered, and evaporated. The residue is treated with diluted acetic acid and nitrite of soda, when a yellow or brown colouration shows the presence of dinitro-benzol in the *original sample*. In three cases a slight indication was found. This was in the case of a man who showed indications of poisoning and who had to leave off working.

A second question which has claimed our attention, and also a large proportion of the chemical trade interested in the practical manipulation of the toluene and benzene group of the nitrated aromatic series, is the comparative danger of *these two groups*. Commercially it is found that some of the toluene group can be substituted for the benzene in the manufacture of certain explosives. The employment of the *benzene group* is surrounded by a number of technical precautions. It is largely and widely becoming the custom where possible to substitute those of the series which are less harmful for those which experience has shown to be the more dangerous.

In an article in THE LANCET of August 31st, 1901, p. 582, a statement was made by one of us that dinitro-toluene is considered highly deleterious and is dreaded by the workmen who are engaged in its production. This settled belief has been repeated to us and it appears to express the general consensus of the opinion of the employés and officials at certain works. Dr. T. M. Legge, H.M. medical inspector of factories, from his large experience of such industries, thought there might be some doubt on this point. We therefore deemed it advisable to experiment upon animals, *with the following results*. To two cats were administered a 1 per cent. solution of dinitro-toluene in cod-liver oil. The quantity given was two cubic centimetres in the morning and two cubic centimetres in the evening daily until each had partaken of 24 cubic centimetres. Neither cat exhibited any symptoms of poisoning. Two weeks later one of the above cats and a second fresh cat were each dosed with a 1 per cent. solution of dinitro-toluene in cod-liver oil, four cubic centimetres in the morning and four cubic centimetres in the *evening until* each cat had received 24 cubic centimetres, with no result except a very slight change in the colour of the mucous membrane.

These experiments prove that to cats dinitro-toluene is rather a harmless drug and if we compare it with the results published in the article in THE LANCET already alluded to where similar doses of dinitro-benzene were administered to cats the contrast is most marked. It must be remembered that these experiments deal with animals, but our experience with allied groups of the aromatic series show a close similarity of action when they are exhibited to animals and men and further industrial experience strengthens our belief that mono- di- and tri-nitro-toluene can be safely manipulated with ordinary precautions.

NOTIFICATION OF CHICKEN-POX.—At the meeting of the Falmouth Corporation held on May 8th it was decided, on the recommendation of the Sanitary Committee, to make chicken-pox a notifiable disease for six months.

is, the periphery is converted into spermatozoa, while the central mass remains undifferentiated. This stage is to be called "sperm mother cell," while the corresponding female body is termed the "egg cell." The result of the fertilisation of the last by the first is the "zygote." The zygote grows and becomes vermiform in shape, exhibiting fairly active movements. To this stage, which is the largest in point of bulk, the term "vermicule" is applied. Up to this point the parasite has remained within the stomach of the gnat. But the vermicule by the help of its active movements pushes or bores its way out of the stomach and gains access to blood-spaces, enveloping that organ, where it acquires a spherical form, enlarges greatly, and surrounds itself with a structureless membrane. This may be called the "cyst" or "spore-cyst." From the breaking up of the protoplasmic contents of this enlarged cell the exotospores arise and the cycle is completed. This latter process is not, however, direct. The cyst at first breaks up into smaller "spore mother cells" from which latter the needle-like exotospores are formed by subsequent division. Professor Lankester's paper concludes with a useful tabular comparison of the stages in the life-history of this hæmosporidian, as the group of the order sporozoa which contains the malaria parasite is called, with the corresponding stages exhibited by the two other subdivisions of the order—viz., the gregarinidea and coccidiidea.

GLAUCOMA FROM A LAYMAN'S POINT OF VIEW.

A COMMUNICATION which will be found in another column of our present issue demonstrates the advantage that may be obtained from an account by an educated layman of his own symptoms in cases of disease. In this instance the affection was diagnosed by the ophthalmic surgeon, Dr C. E. Glasscott of Manchester, under whose care the patient placed himself, as one of chronic glaucoma, and a grave forecast of the result was given. This view was subsequently supported by Professor A. Maitland Ramsay and was fully borne out by the progress of the disease. The patient, who seems to have been one of the victims of the struggle for existence in these days, was originally strong and vigorous and could, he tells us, cover 30 miles in a day without distress. He attributes the onset of the glaucomatous symptoms to a combination of constant mental worry and excitement, over-exertion of the eyes in literary work, and the damp and cold climate of the North-west of England. He gives a graphic account of the early stages of the disease, including the ciliary neuroses, fogs, and obscurations of vision and flashes of light that are so commonly observed. Various symptoms mentioned, however, seem to show that the case was not one of pure glaucoma, but that the central nervous system was more or less implicated, as, for example, the kind of paralysis of the nose, the lips, and the chin, making speech occasionally quivering, the periodical numbness of the forehead, and the occurrence of fantastic designs, figures, and phantasmagoria which do not commonly accompany glaucoma. No mention is made throughout of increase of tension in the eyes, though the patient must often enough have been tested to determine this point and must have perceived the importance attached to it by his medical attendants. Presuming the globes to have been normal or subnormal we think that a wise conclusion was arrived at in abstaining from the performance of iridectomy or any of the substitutes for that operation. At the same time it is easy to conceive that differences of opinion in regard to the cause and nature of the disease might have led to different modes of dealing with it in the hands of different practitioners. We have, however, no desire to comment on the treatment pursued, but we have published the case as extremely interesting because it is rare to meet with a clear account of the progress of any disease from the patient himself, and where such patient is intelligent symptoms may be noticed which the surgeon might easily overlook but which might afford valuable hints in regard to treatment.

SMALL-POX IN LONDON.

THE returns of small-pox for the past week are as follows: On Saturday, March 29th, there were 48 fresh cases notified and removed; on Sunday, the 30th, there were 46 fresh cases; on Monday, the 31st, there were 61 fresh cases; on Tuesday, April 1st, there were 62 fresh cases; and on Wednesday, the 2nd, there were 57 fresh cases.

THE CONTINENTAL ANGLO-AMERICAN MEDICAL SOCIETY.

A PROPOSAL by Dr. F. H. Burton-Brown (of Rome) was laid before the annual meeting of the Continental Anglo-American Medical Society that a luncheon of the society should be held every year at the meeting of the British Medical Association. A special committee was then appointed to consider how far the proposition could be carried out with a prospect of success. Any members of the society who propose to be present at the annual meeting of the British Medical Association to be held at Manchester in July, 1902, are requested to write to that effect before leaving their winter quarters to one of the members of the special committee: Dr. D. W. Samways, Place St. Roch, Mentone; Dr. Leonard N. Robinson, 1, rue d'Aguesseau, Paris; and Dr. StClair Thomson, 28, Queen Anne-street, London, W.

ACHONDROPLASIC DWARFS, HISTORICAL AND PREHISTORIC.

DR. FELIX REGNAULT has recently published an interesting study of the action of achondroplasia in producing dwarfism not only in the human subject but among the lower animals as well. His article, which is profusely illustrated and fills 24 pages of the February number of the *Archives Générales de Médecine*, does not deal with living examples but with museum specimens, individuals of whom historical accounts or portraits are extant, ancient Greek or Roman statues, and pictorial representations on Egyptian monuments. In the achondroplasic fœtus the long bones are shortened and thickened and the deviations from the normal straightness which they present are not gradual curvatures but are obviously angular; the resulting appearances are distinguished from the effects of intra-uterine fractures by the fact that in achondroplasia the bendings of the bones are symmetrical on each side at the same level; the deformities produced by intra-uterine rickets differ also from those of achondroplasia, for the former are gradual curvatures of considerable radius. In achondroplasia the facial bones seem to recede and the forehead to project, the nasal bones being at the same time flattened. In adult subjects the shortening of the long bones is more pronounced in the humerus and the femur than in the radius and the tibia and the three middle fingers are of equal length; the skull is large and brachycephalic; the facial and nasal bones are as already described. Among the dwarfs whose likenesses have been preserved from past generations Dr. Regnault distinguishes those whose condition was due to achondroplasia on the one hand or to myxœdema on the other. Two of his achondroplasic dwarfs are (1) Owen Farrel, an Englishman who died in 1742 and whose portrait is in the Royal College of Surgeons of England; and (2) Sebastien de Morra, a servitor of Philip IV. of Spain. Two of his myxœdematous dwarfs are Tom Thumb and Simon de Paap, a Dutchman who was exhibited in the early years of the nineteenth century. Among the ancient Egyptian deities the figure of Phtah is

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF RODENT ULCER OF THE NOSE AND EYELIDS TREATED WITH THE X RAYS.

BY G. G. STOPFORD TAYLOR, M.D. DURH.,

HONORARY PHYSICIAN TO THE LIVERPOOL SKIN HOSPITAL.

DURING the last 18 months I have treated a number of inoperable cases of rodent ulcer by the x rays with varying success. Some of them have equalled the following case but none have excelled it.

The patient in question was introduced to me by Dr. E. Adam. He was 82 years of age and had been employed in the mercantile marine. His previous history was as follows. For 20 years or more he had suffered from a small chronic ulcer on the right side of his nose which caused him much pain. He was treated with the usual remedies but without any benefit. Six years ago Dr. Adam brought him to me and I applied potassa fusa but failed to effect a cure. I have no record of the exact appearance of the ulcer at that time but when Dr. Adam brought him again in May, 1901, the disease presented the typical rolled edges of a rodent ulcer. It had much increased in size, extended to the inner angle of the orbit, and had destroyed portions of the lids together with the lacrymal canals and caruncle. The patient was in much pain.

Treatment was begun on May 15th. A current of three ampères was used for 20 minutes twice weekly. From June 12th the sittings were increased to four times a week. Up to about August 19th healing had been very slow, but on this date treatment had to be suspended because of the sharp reaction, indicated by a sudden appearance of a dusky red erythema surrounding the ulcer, attended by the destruction of the newly-formed epithelium upon its surface and of the surrounding epidermis, brought about, I think, by change of the x ray tubes from one of high vacuum to one of medium vacuum. It took five weeks for the effects of this reaction to disappear, when spontaneous healing began and was very rapid, for on Oct. 15th the ulcer had cicatrised with the exception of a small area which proved obstinate and where, I believe, I had made the application of potassa fusa six years previously. On this date treatment by the x rays was resumed, but they were applied to this unhealed spot only for 10 minutes three times weekly, the newly formed scar tissue being specially protected from their action with double lead foil shields.

Treatment was completed by Dec. 20th. At that time there was not the slightest evidence of the disease, neither has there been any recurrence. It is interesting to note also that the conjunctiva of the everted lower lid and that of the inner canthus was covered with a smooth layer of opaque horny epithelium and no trace of the puncta remained.

The patient was shown at the Liverpool Medical Institution on March 13th.

Liverpool.

A CASE OF MALFORMED FŒTUS.

BY NICOLAS ELRINGTON, L.R.C.P. LOND., M.R.C.S. ENG.

A PATIENT under my care, a labourer's wife, gave birth recently to a curiously malformed child. The body was well developed and the lower part of the face was that of an ordinary full time child. The frontal bones were widely separated and were flattened back so as to be almost at right angles to the face. The eyes were very far apart and the eye balls protruded. The parietal bones were small and what should have been their upper margins were pointing almost directly backward. The occipital bone was only represented by two small strips of bone lying close to the posterior edges of the parietal bones. All the cervical and the upper five or six dorsal vertebræ were apparently wanting. The chin rested on the second piece of the sternum, the ears, which were abnormally large, lay in front of the shoulders. The back of the head and the neck was occupied by a mass of freshly formed blood-clot which in one place had burst through the skin, there was no hair and the skin of the head was very thin.

The labour occurred at full term and the mother was certain that the child was alive two hours before her pains began which they did only three hours before the child was born. I had to be content with an external examination and consequently I cannot say what was the condition of the brain and the spinal cord. There was nothing during the pregnancy out of the ordinary except the amount of liquor amnii which was very excessive. I think that there is no doubt that the child died from the effect of pressure during parturition. The presentation, as may be imagined, was somewhat bewildering but the progress of the labour was very rapid and the child was born with the chin presenting under the symphysis pubis without any difficulty.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

LONDON TEMPERANCE HOSPITAL.

A CASE OF SOLID OVARIAN TUMOUR, LAPAROTOMY, ENUCLEATION, RECOVERY.

(Under the care of Dr. W. J. COLLINS.)

SOLID tumours of the ovary are much less frequently met with than are those which are cystic. The exact proportion is doubtful, but Bland Sutton's estimate of 5 per cent.[1] is probably fairly correct. The malignancy of the ovarian tumours which are called sarcomata from the histological appearances varies within very wide limits, in some removal of the tumour is not followed by any recurrence even after several years, while in others early and extensive recurrence occurs, and yet no obvious histological difference may have been noticed in the growths. A very guarded prognosis must always be given.

A woman, aged 26 years, was admitted into the medical wards of the London Temperance Hospital on May 5th, 1901. She had been married for three years, she had one child two years old, and menstruation had been regular up to April, 1901. On May 4th she was suddenly seized with severe abdominal pain and was sick and faint. There had been no period from April 10th up to the time of admission. On admission the abdominal pain continued, there were tenderness and resistance in the lower abdomen, more on the left side than on the right. The general condition was good and her appearance was healthy. The temperature in the evening was 102.8° F. On the 5th it was noted that the cervix uteri was soft and patulous and that the pelvis was occupied by a nodular mass. Five days later bimanual examination revealed a tumour reaching as high as the umbilicus, where a sharp edge could be detected, and extending with less definition into the left lateral fornix, the tumour was moveable and appeared to be distinct from the uterus. On the 21st the abdominal swelling was found to be enlarging and it gave rise to considerable discomfort. Moreover, curious nodules and pedunculated parts were detected which raised a suspicion of extra-uterine pregnancy. On June 7th there was what appeared to be a normal catamenial discharge. Dr. Collins was asked to take over the case and on the 21st, under chloroform, he performed median laparatomy, exposing a solid tumour which appeared to spring from the right ovary. The growth seemed to be sessile, springing from a broad base, but with a little difficulty and care the whole tumour was cleanly enucleated. There was very little hæmorrhage. The left ovary contained a small recent corpus luteum but was otherwise healthy.

---

[1] Tumours, second edition, p. 123.

The tumour weighed three pounds six ounces and microscopically was a spindle-celled sarcoma. The peritoneum, muscles, and skin were separately sutured with silk; no drainage was employed. The healing of the wound was uninterrupted, with the exception of a small stitch abscess at the inferior extremity of the incision, but the temperature rose to 102° and continued high during three or four weeks owing to some pleurisy on the left side and on July 14th a small collection of sero-purulent fluid was incised and drained from the left pleura. The patient was discharged quite well on August 25th and recent reports from her have been entirely satisfactory.

Remarks by Dr. COLLINS.—The history and some of the symptoms on admission in this patient naturally raised *primâ facie* the question of "hæmatocele" or rupture of an early extra-uterine fœtation. The subsequent bimanual examinations, when more defined portions of the tumour were detected, led some who saw her to think that they could recognise definite fœtal parts; moreover, some lactiform fluid was derived from the nipples. Although one catamenial period had been missed there had been no irregular metrorrhagia and on June 7th a normal period commenced. Nevertheless the case was not free from doubt and as the patient's discomfort was increasing it seemed at least prudent to explore the abdomen. The tumour was of a reddish colour, more like a fibroid than an ovarian cystoma, and exhibited irregular and fantastic extensions of varying density both across the pouch of Douglas and towards the abdomen. The ease with which the mass was enucleated was surprising considering the appearance it gave, at first sight, of an unpromisingly broad pedicle.

NORTHAMPTON GENERAL INFIRMARY.

A CASE OF LOCALISED DISEASE IN THE OPTIC THALAMUS; SOFTENING AND HÆMORRHAGE; DEATH; NECROPSY.

(Under the care of Dr. FRANK BUSZARD.)

IN the present state of our knowledge of the functions of the basal ganglia the value of carefully described cases of lesions affecting these structures cannot well be overrated. In the following case the symptoms were very striking, and the post-mortem account is very clear, though no mention is made of the presence or absence of a clot in the veins of Galen. Dr. E. W. Goodall has related in the Transactions of the Clinical Society of London,[1] a case in which softening of both optic thalami occurred, with thrombosis of the veins of Galen. In that case, as in the one recorded below, there was hyperpyrexia just before death.

The patient was a woman, a multipara, 53 years of age. About a year previously to the onset of the present illness she was said to have had a "stroke" which affected her left arm chiefly, but from which she in three or four weeks completely recovered; with the exception of this she had always enjoyed good health. On the night of August 24th, 1901, she went to bed apparently well. On the following morning her husband stated that he could not get her to answer questions; she appeared to be very dazed and her face was drawn. She was admitted to the Northampton General Infirmary on August 30th. During the interval of one week which had elapsed between the date of the onset of the symptoms and her admission she appeared to have been in a very drowsy state; there was no vomiting during that time, or, indeed, throughout the whole illness. On admission the patient, who was somewhat wasted and looked much older than her years, appeared to be very drowsy and could only be roused with difficulty. She lay for the most part on her left side and answered questions but only in a very slow manner. She recognised objects to which her attention was drawn and named them correctly. The speech was blurred and indistinct and articulation was difficult, syllables being slurred together as in general paralysis of the insane. There were continuous "champing" movements of the jaws. The jaws and tongue were in constant movement as in the acts of mastication and deglutition, and these movements continued without cessation for 10 days, except during sleep. There was no difficulty in swallowing; slight left facial weakness was present. The pupillary reflexes were normal, there being no strabismus, nystagmus, or fundus change. Owing to the mental condition of the patient it was not possible to obtain any definite information with reference to alteration in the fields of vision. Neither the arms nor the legs showed any signs of paralysis. The arms, like the jaws, were never at rest but were the seat of constant athetoid movements which were unusually irregular and at times rhythmic. Tremor of the arms and hands was only present on voluntary movements. They were markedly ataxic and on the patient being told to do anything—e.g., to touch the nose with the index finger of the right hand—the act, which she did with difficulty, would be repeated time after time until she was told to stop, or on other occasions the finger and hand were kept in the new position and were not removed for some time. There was no paralysis or abnormal movement of the lower limbs. She was unable to stand without support, being unsteady and swaying about a great deal. Sensation was normal. The knee-jerks were brisk; there was no ankle clonus; the plantar reflexes were normal. The urine and fæces were passed into the bed. The pulse-rate ranged from 70 to 80, the respirations were 20, and the temperature was 99° F. The urine was normal; the tongue was furred.

From August 30th to Sept. 5th the condition of the patient remained the same. The movements of the jaws and arms never ceased except during sleep, the mental condition perhaps slightly improving. Pyrexia was present to a small extent, the evening temperature ranging from 99° to 100°. On Sept. 5th conjugate deviation of the eyes to the right was first noticed and this persisted until the day of death. From the time she first came under observation there was a tendency for the eyes to wander to the right and she kept them in this position for the most part, although moving them when her attention was directed. She became more apathetic and on the 10th she relapsed into a state of coma. The movements of the jaws and arms ceased and she lay on her left side with the eyes open and turned to the right until the 12th when the temperature ran up to 105·9° at 6 P.M. and she died at 11 P.M.

Necropsy.—A post-mortem examination was made 12 hours after death. With the exception of a little hypertrophy of the left ventricle of the heart and extensive atheromatous changes in the aorta, the thoracic and abdominal organs were normal. On removing the skull-cap the membranes were found to be normal; there was no meningitis or bulging or flattening of either cerebral hemisphere. The vessels at the base of the brain, and particularly the middle cerebral arteries, were in an advanced stage of atheromatous and calcareous degeneration. No clotting in the right middle cerebral artery was observed. On making horizontal sections into the brain and laying bare the basal ganglia the right optic thalamus was seen to be swollen and distended, bulging more than the left optic thalamus into the third ventricle. The left optic thalamus was atrophied; on section it was brownish in colour and firmer than normal. On cutting into the right optic thalamus its interior was found to be occupied by a blood-clot, which, however, was strictly confined to the thalamus and did not in any way involve the internal capsule or corpus striatum. The substance of the thalamus surrounding the clot was in a condition of red softening. It was thought probable that a thrombosis had occurred at the date of onset and had caused softening to occur in the optic thalamus and that a hæmorrhage had secondarily occurred on Sept. 10th, the day on which the coma developed. No blood or excess of fluid was discovered in the ventricles.

Remarks by Dr. BUSZARD and Dr. W. BERTRAM WATSON.—Among the various physiological problems which the neurologist has to face there are perhaps none more complex than those associated with the basal ganglia of the brain. The experimental observations which have been made are in many cases uncertain and conflicting and it is rare to find cases clinically in which the lesions are so definitely localised as to be of any value in arriving at a correct decision as to the functions of the parts concerned. The chief interest of the case which we have just described lies in the fact that the lesion found at the necropsy was apparently strictly confined to the right optic thalamus, although one cannot entirely exclude the possibility of there having been during life some pressure upon the surrounding structures. The salient features of the case were: (1) "champing" movements of the jaws; (2) athetoid movements of the arms; (3) conjugate deviation of the eyes; and (4) thermal disturbance. In connexion with (1) we may cite the experiments performed by Bechterew[2] who found that stimulation of the optic thalami in rabbits set in action a complex of movements necessary for the nutrition of the organism, beginning with those of mastication and deglutition and ending with those of the bowel. (2) An interesting feature of this case was that the athetoid movements affected both sides of the body and were not, as is more common, solely confined to the side opposite to the lesion in the optic thalamus. In this connexion we may refer to the experiments by Nothnagel,[3] *who found that animals in which the* optic thalami were destroyed on both sides seemed to have lost the sense of the position of their limbs, since without being paralysed they allowed them to remain in any position in which they were placed. (3) It is probable that the conjugate deviation of the eyes, as also the left facial weakness, was due to irritation of the internal capsule. (4) It is noticeable that there was no considerable elevation of temperature until the last, when hyperpyrexia set in. It is possible that the latter event resulted from the hæmorrhage into the optic thalamus, leading to pressure upon the corpus striatum, for Hale White, in his experiments,[4] came to the conclusion that lesions of the optic thalamus do not cause pyrexia, whereas irritative lesions of the corpus striatum do.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY

An Analysis of Forty-six Tabulated Cases of Cancer of the Breast.

A MEETING of this society was held on May 13th, Mr. ALFRED WILLETT, the President, being in the chair.

Mr. THOMAS BRYANT communicated a paper entitled "An Analysis of Forty-six Tabulated Cases of Cancer of the Breast which have been Operated Upon and Survived the Operation from Five to Thirty-two Years." The objects of the communication were: (1) the prospects of life after primary operations for cancer of the breast; (2) the question of recurrence of the disease at the seat of the primary operation and the second breast; and (3) the nature and effects of operation upon the progress of the disease. Mr. Bryant had always felt that the three years' freedom from recurrent disease after a primary operation which had been laid down as an indication of a cure of cancerous disease, was not only unreliable but misleading, and he had repeatedly demonstrated this. He proposed to divide his cases into three groups. Group I. of the cases included 17 cases of cancer of the breast relieved by operation which were now alive or had died without evidence of recurrent disease five or more years after operation. Taking the whole group of 17 cases together there was an absence of any evidence of recurrent disease from five to 10 years after the primary operation in nine cases and from 10 to 20 years in eight cases. 13 of these patients were now alive and apparently well. Mr. Bryant's routine operation was to remove the whole mammary gland with the skin and fat over the diseased area, and in every case, for examination purposes, to cut into the axilla and to take away glands or lymphoid tissue which appeared to be suspicious. The pectoral muscle he dissected clean but he did not remove it unless it were invaded by disease. He regarded the removal of the muscle as a routine measure to be unnecessary. *Group II.* included 19 cases of cancer of the breast relieved by operation and followed by recurrence in the seat of the primary operation. In three of the cases recurrence took place in the scar of the primary operation and a second operation was performed one year after the primary; two of these three cases were well and in good health four years later and in the third case 10 years later. In nine cases recurrence occurred from three to seven years after the primary operation. In three of these no second operation was called for. Group III. included 10 cases of recurrent disease after operation in which the second breast was involved and four cases in which the breast disease was associated with cancer of other parts of the body. Looking at the tables submitted as a whole it was evident that the interval which might take place between the primary amputation of a breast for cancer and its recurrence in the scar or the second breast, when such occurred, was most uncertain. That whilst in half the cases tabulated recurrence took place in five years or less, in the second half the interval before recurrence appeared varied from six to 32 years, and that in at least two-thirds of these cases it occurred after 10 years. With respect to the *seat of the recurrence* it seemed that this was in or about the scar of the original operation in 14 cases; in the scar and axilla in only one case; in the sternum in three cases; in the second breast in 10 cases, and in five of these 10 the scar of the first operation was likewise involved. In only one case was the axilla cleared out in an operation for a recurrent affection. It was not his custom to clear it out in all, and yet these results did not suggest an inadequate operation. It was shown that operations for cancer of the breast, when undertaken at an early period of the disease, were not so unsatisfactory in their ultimate results as was generally believed. In cases of recurrence not favourable for operation unless the removal of the ovaries could be shown in the future to be successful the x rays should be employed, for the benefit which had been derived by this treatment when judiciously applied by men of understanding had in his experience been so successful as to raise hopes which he hardly liked fully to express and at the same time seemed to be free from danger or serious consequences when utilised by those who knew the dangers of penetrating rays carelessly employed and the difficulties with which the practice bristled. The influence of the rays, to make them effective, must be maintained for several months after it had seemed to be beneficial; a three months' course with about three applications a week appeared to be the shortest from which any permanent good was to be expected.

Sir WILLIAM M. BANKS congratulated Mr. Bryant on his paper. He (Sir William Banks) had had a wide experience of mammary cancer. In former times 10 out of every 100 cases he operated on died. This was due to the insanitary state of the hospital in which the operations were done. The hospital was rebuilt and now out of between 90 and 100 cases there had only been one death. Anything more erroneous than the rule that cancer cases could be regarded as "cured" after three years of non-recurrence could not be imagined. Out of 58 cases which he had operated on and which he had followed up with the greatest care, six cases died from local recurrence (four in from five to 10 years and two in 12 and 14 years). 12 cases died from general but no local recurrence (nine of these cases lived from five to 10 years and three died at 10, 10, and 14 years respectively). In 12 cases there was no return, the patients living from five to 18 years; 14 patients were still alive and well after from five to 10 years, 12 after from 10 to 20 years, and two after from 20 to 23 years. It was most essential to take the case for operation early. That was the most important point in the whole matter. The disease, in his opinion, came back in the lymphatics of the skin around the scar and therefore it was very important to remove the skin liberally at the time of operation. Halsted's operation was wholly unnecessary. When the cervical glands were involved the case was beyond the reach of surgery; when they were not such an operation was both dangerous and unnecessary.

Mr. BRYANT, in reply, agreed with Sir William Banks that the large and so-called "adequate" operations were dangerous and wholly unnecessary. It was possible to do all that surgery could do by more moderate means.

Mr. HICKMAN J. GODLEE communicated a contribution to the study of Tropical Abscess of the Liver which will appear in our columns next week with the discussion thereon.

MEDICAL SOCIETY OF LONDON.

Annual General Meeting.—The Diagnosis of Malaria from the Standpoint of the Practitioner in England.—Election of Officers.

A MEETING of this society was held on May 12th, Dr. W. H. ALLCHIN, the President, being in the chair.

The annual report of the council setting forth the work of the society was presented. The librarian's report referred to the gradually increasing use which the Fellows were making of the library. Dr. J. B. NIAS had been engaged on the work of examining the Greek MSS. belonging to the society. The House and Finance Committee presented its report. All these reports were unanimously adopted.

[3] Topographische Diagnostik der Gehirnkrankheiten, 1879.

[4] Alteration in Bodily Temperature in Lesions of the Brain: Brit. Med. Jour., 1891, vol. i., p. [illegible]

Dr. PATRICK MANSON, C.M.G., gave an address on the Diagnosis of Malaria from the Standpoint of the Practitioner in England which appears in full at p. 1377 of our present issue.

The PRESIDENT warmly congratulated Dr. Manson upon the valuable and practical address delivered before the society and after a few remarks by Dr. C. E. BEEVOR and Dr. T. D. SAVILL, Dr. MANSON briefly replied.

The following gentlemen were elected to the several offices mentioned for the session 1902-3: President: Mr. A. Pearce Gould. Vice-Presidents: Dr. Thomas T. Whipham, Mr. Charles A. Ballance, Dr. Frederick S. Palmer, and Mr. Henry Morris. Treasurer: Dr. David H. Goodsall. Librarian: Dr. Arthur Francis Voelcker. Honorary Secretaries: Mr. Jonathan Hutchinson, jun., and Dr. Henry A. Caley. Honorary Secretary for Foreign Correspondence: Dr. Humphry D. Rolleston. Council: Dr. William Henry Allchin, Sir William M. Banks, Mr. Arthur E. Barker, Mr. J. Bland-Sutton, Dr. Charles W. Chapman, Dr. J. Walter Carr, Mr. Frederic Durham, Dr. William Ewart, Dr. Robert A. Gibbons, Dr. Samuel H. Habershon, Mr. Walter H. Jessop, Mr. Howard Marsh, Mr. C. W. Mansell Moullin, Dr. Isambard Owen, Dr. H. Campbell Pope, Dr. Arthur H. Robinson, Dr. J. S. Risien Russell, Mr. Edgcombe Venning, Mr. Herbert F. Waterhouse, and Mr. Edwin F. White.

CLINICAL SOCIETY OF LONDON.

Congenital Lymphangioma terminating in Lympho-sarcoma — Primary Sarcoma of Synovial Membrane.—"Horizontal" Dilatation of the Left Auricle.—Intercostal Pulsation in a Case of Mitral Stenosis.

A MEETING of this society was held on May 9th, Mr. HOWARD MARSH, the President, being in the chair.

Mr. W. G. SPENCER read a paper on a case of Congenital Diffuse Lymphangioma terminating in Lympho-sarcoma after Lymphangitis with a Continuous Hectic Fever for three months affecting the lower extremity of a girl, aged four years. The patient was born with the right leg longer than the left. It caused no uneasiness until without any assignable cause it became swollen by inflammation immediately before coming under observation. For the three months preceding death there were marked and continuous hectic fever, and an evening temperature of 103° F., with a fall to a subnormal morning temperature of 97° F. or even 90° F. The pulse throughout was about from 130 to 140, on many days rising to 170 or even 180 per minute. First the leg, then the thigh, and finally the hip, the loin, and the groin became swollen. There was no change in the skin, but small incisions allowed serous fluid to escape, containing fibrinous casts of the dilated lymphatic spaces. No chylous fluid ever escaped, nor did lymph vesicles form on the skin, nor did the skin become rugose. At the necropsy the swelling of the thigh and hip region was found to be due to dilated lymphatic spaces with intercystic masses of lympho-sarcoma, as shown in microscopical sections. Other cases, including macroglossia, in which congenital lymphangioma had terminated in lympho-sarcoma, were mentioned.—Dr. H. D. ROLLESTON asked what were the naked-eye evidences that the morbid growth was lympho-sarcoma? Lympho-sarcoma had well-defined macroscopical and microscopical characters, and in the specimens under the microscope he did not recognise the definite reticulum and other features belonging to this neoplasm. The case before the society resembled sarcoma which had arisen in lymphatic glands.—Mr. SPENCER, in replying, referred to the temperature records and clinical history, and said that the secondary growths all consisted of the small round-cell growth supported by a reticulum, so typical of lympho-sarcoma.

Mr. G. R. TURNER communicated a case of Primary Sarcoma of the Synovial Membrane of the Ankle-joint. The patient was a man, aged 28 years, who two months before admission into St. George's Hospital knocked his foot against a brass screw. Three weeks after this he noticed a swelling in front of the right ankle. This had slowly increased in size and measured about one and three-quarters by one and a half inches. There was no obvious connexion with the tendons. When removed it was found to be growing from the synovial membrane of the ankle-joint. Dr. Rolleston had examined the tumour and had reported it to be a fibrifying and chondrifying mixed-cell sarcoma. Attention was drawn to the rarity of *primary* sarcoma of the synovial membranes. Myelomata of tendon sheaths were much more commonly met with and were innocent clinically. Reference was made to a case recorded by Mr. Howard Marsh of primary sarcoma of the synovial membrane of the knee-joint. Mr. Turner's patient had been exhibited at a clinical meeting of the Clinical Society of London in the early part of this year.

Mr. C. B. LOCKWOOD communicated a case of Sarcoma of the Synovial Membrane of the Knee-joint. The patient was a young married woman who had had disease of the right knee of three years' duration. The joint was slightly flexed but possessed almost its full range of movement. The capsule was distended by a swelling of the synovial membrane which made the circumference of the joint three-quarters of an inch greater than that of its fellow. The surface of the swelling was rather warm and it was tender on pressure. A consultation was held and the opinions were almost unanimously in favour of the disease being tuberculous. As no treatment had been tried it was thought well to rest the joint and to apply a splint. Nothing was seen of the patient for about a year when she returned with what appeared to be well-marked tuberculous disease of the knee. A resection was performed and the absence of any evidences of caries and of pus excited some suspicion. The material was examined by two pathologists and was pronounced by one to be "spindle-celled sarcoma" and by the other to be "oval-celled sarcoma." Mr. Lockwood discussed the diagnosis and adverted to the very close resemblance which the symptoms presented to those of tuberculous joint disease. In fact, when the case was first seen there were only two points which might have excited suspicion that the disease was not tuberculous: (1) the absence of muscular wasting; and (2) the free and painless mobility of the joint after having been the seat of disease for three years. There was no doubt, however, that the case was one of sarcoma starting in, and involving, the synovial membrane.

The PRESIDENT, in the discussion on these two papers, referred to the case which he had reported in the thirty-second volume of the Transactions of the Clinical Society of London. The patient, a man, aged 21 years, was admitted into St. Bartholomew's Hospital on account of a swelling in the knee which had existed for 15 months. When the knee-joint was opened the growth was found to be surrounded by synovial membrane. The growth was removed and recurrence took place five times, the first time after three years, and the last time six years from the time he came under observation. On the last occasion the leg was amputated. It was remarkable to note how the growth successively affected different portions of the synovial membrane. Microscopical examination showed that it was a spindle-celled sarcoma. The patient was at the present time alive and was free from any return of the disease. By a curious coincidence he was in the hospital a few days ago with consolidation in one lung. Knowing his history it was feared that the lung was the seat of growth, but the lung trouble had cleared up. A short time ago the President had seen a young woman, aged 22 years, with a condition very like that found in Mr. Turner's case, except that the tumour was in the knee. When the joint was opened the growth was almost pedunculated. It proved to be a sarcoma. Mr. Lockwood had dwelt on a very important point—namely, the obscurity of the diagnosis in these cases. He had remarked that the temperature had led him to suppose that the disease was tuberculous, but this was not really a trustworthy guide in differential diagnosis, because malignant growths in joints were not infrequently found to be associated with high temperature.—Mr. SPENCER called attention to an important point of difference between Mr. Lockwood's case and those of Mr. Turner and of the President. In the former the growth was diffused, whilst in the latter it was localised. The President's case appeared to resemble a class of tumour recently referred to in another society as "endotheliomata." With regard to diffuse growths in the synovial membrane as distinct from tuberculosis he had seen two cases which were put down as "rheumatic" without any sufficient evidence for this view. Mr. J. Hardie of Manchester had described in THE LANCET of June 30th, 1894, p 1619, a sarcoma occurring in the synovial membrane of the knee-joint. These rarer forms of sarcoma affecting synovial membrane appeared to run a different course from that observed in the case of sarcoma attacking bones.—Mr TURNER, in reply, said that the discussion had shown, as Mr. Spencer had pointed out, that these sarcomata were of two kinds, the circumscribed and the diffuse. In his case tuberculosis was not even thought of before operation, the diagnosis lay between some kind of new growth and a bursal cyst.—Mr. LOCKWOOD also briefly replied, laying emphasis on the mobility of the joint as a means of diagnosis from tuberculous disease.

Dr. WILLIAM EWART and Dr ISAMBARD OWEN communicated a case illustrating the clinical feature of "Horizontal" Dilatation of the Left Auricle. This condition had been brought before the Clinical Society of London by Dr. Isambard Owen and Dr W. J. Fenton in 1901.[1] In that case enormous dilatation of the left auricle took place outwards and towards the right and it was remarkable how little pain and what few subjective symptoms were exhibited with the lesion The diagnostic features of the condition were systolic pulsation (synchronous with the apex beat) in the right fourth intercostal space, great increase of the precordial dulness transversely even to, or beyond, the right mammary line, a similar increase in the post-cordial dulness, occasional pulsation of the liver, and cyanosis and dyspnœa without anasarca or dropsy of the serous cavities. Dr. Ewart and Dr. Owen commented on the latency and insidiousness of the affection and hoped in the future to be able to diagnose the condition by skiagraphy Rest and venesection seemed to be important means of treatment.

Dr. ISAMBARD OWEN also contributed a paper on "Horizontal" Dilatation of the Left Auricle, with special reference to other cases and specimens besides the one which he had exhibited with Dr. Fenton[2] in May, 1901. Inquiries at all the principal museums and medical schools in the United Kingdom had shown that only three other specimens were known to be in existence, one of these was at St. Bartholomew's Hospital and one at University College. These were briefly described, after which Dr. Owen compared and contrasted the most important clinical and pathological features of the three cases In all these cases the pericardium was adherent and in none of them was there any definite lesion of the mitral orifice. In one of these cases it was possible to place a rod eight inches long transversely in the auricle, thus resembling his (Dr Owen's) original case which presented in the right axilla and had been mistaken for pleural effusion. He (Dr Owen) thought the term "horizontal dilatation" appropriate to distinguish this rare condition from the more usual spherical or vertical dilatation —Dr ARTHUR F VOELCKER, referring to the case under Dr. Ewart's care, asked if there was a murmur in the tricuspid area, because he thought the pulsation observed in the fourth right interspace might be derived from the right auricle rather than the left. The pulsation of the liver supported this contention.—Dr. W. P. HERRINGHAM entirely concurred with the last speaker as regarded the pulsation observed He thought all the signs described in Dr. Ewart's case might be produced by dilatation of the right auricle, excepting the percussion signs at the back, which needed confirmation. There were some discrepancies in the charts of posterior percussion dulness exhibited which needed explanation.—Dr. EWART, in reply, admitted that the right auricle in his patient might also have been dilated. Pulsation systolic in rhythm was not met with in connexion with right auricular enlargement. He relied on other symptoms also for the diagnosis of the condition and the absence of the secondary evidences of cardiac failure on the right side of the heart, such as dropsy in the serous cavities and anasarca.

Dr. EWART communicated a note on Palpable Systolic Intercostal Pulsation in a case of Mitral Stenosis with Dilatation and Thrombosis of the Left Auricle occurring in a woman, aged 24 years. The purport of the communication was to elicit further information concerning the significance of systolic pulsation of the right auricle, its diagnostic value, and frequency of occurrence

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases, &c —20 Cases of Gastro-Enterostomy performed for Intrinsic Stenosis and Tumour of the Pylorus.—Cyto-diagnosis of Pleural Effusion.

THE ninth ordinary meeting of this society was held on May 7th, Professor T. R. FRASER, F.R.S, the President, being in the chair.

Professor HENRI HUCHARD of Paris was elected a corresponding member of the society

Dr. NORMAN WALKER exhibited four patients treated by various methods of Photo-therapy

Mr. H. ALEXIS THOMSON demonstrated a patient after removal of Hyperostosis of the Upper Jaw and Malar Bone of the left side. The condition was congenital but the increase in size of the jaw had been greater since the girl was struck by a stone some years previously The bony excretion was removed by an incision much the same as that employed in removing the upper jaw. The bone was found to be very soft and cut like hard cheese.

Dr. R. MCBRIDE showed a girl the Bridge of whose Nose had been Restored by Injecting Paraffin.

Mr. HAROLD J STILES exhibited the following cases 1. A boy after operation for large Intradural Abscess following middle-ear disease. The boy was admitted to hospital four weeks previously suffering from slight paralysis of the left arm and with a discharging sinus on the right side of the scalp. The probe passed down through the skull and into the cranial cavity In November of last year the boy had suffered from an ordinary middle-ear catarrh. Subsequently he had a convulsion with paralysis of the left arm About a week previously to his admission a large abscess formed in the fronto parietal region and this was opened. There were now complete optic atrophy of the right eye and partial optic atrophy on the left side. At the operation a large abscess was found between the meninges the result of leptomeningitis secondary to the ear disease. The boy had improved greatly. 2. A girl after treatment of Congenital Dislocation of the Hip by Lorenz's method. The case showed the great importance of early diagnosis of such cases as cure depended on their early treatment.

Dr A. BRUCE showed the following cases. 1 A woman suffering from Complete Paralysis of Conjugate Deviation of the Eyes to the Left with almost complete retention of such movements to the right. There was slight left facial paralysis. The condition resulted from a fall. The lesion was necessarily of the sixth nucleus. Convergence of the eyes was retained. 2. A woman with Spasm of Convergence. She had become run down in health and had suffered from dimness of vision, at first only once in a few days, but latterly this had become more frequent and then remained permanently when she looked at a near object This condition of spasm of convergence could not be unlocked until light was excluded from the eyes. 3 and 4 A girl, aged 12 years, and a boy, aged nine years (brother and sister), who were suffering from Spastic Paralysis following Pertussis. Until five years ago they were in perfect health, when they took whooping-cough The boy had a convulsion at that time. About a year subsequently to the pertussis the boy began to suffer from weakness of one leg and later of the other. The girl soon followed in a similar way Both became unable to walk and their mental condition also deteriorated. The boy exhibited the attitude of spastic paraplegia but these cases were not congenital. In both the knee-jerks were very exaggerated and ankle clonus was present. The cause was probably syphilis, as in both the teeth were typical and the forehead was characteristic. There was probably a meningeal thickening producing atrophy of the cortical centre for the leg and of the intellectual centres also. The pertussis was probably a mere predisposing cause

Dr W. G SYM showed a girl who had Double Vision when looking to the right and especially when looking down and to the right. A spasmodic contraction of the right inferior rectus was the only condition which could give such an affection.

Mr J. M. COTTERILL showed the following cases 1 A woman with Multiple Scirrhus treated by oöphorectomy and the x rays. The right mamma was removed in June, 1900, but the growth recurred in the cicatrix as numerous nodules The left breast was also the seat of cancer as were the glands in the axilla and the neck. As removal was out of the question oöphorectomy was performed. Great improvement went on for four months when menstruation recurred and the tumours began to grow afresh. Dr. Dawson Turner had employed ultra-violet rays for five minutes every second day with excellent effect on the nodules on the right side. There were secondary nodules down the back and over the scalp. 2. A child with Multiple Tuberculous Arthritis (four large joints).

---

[1] Transactions of the Clinical Society of London, vol. xxxiv., p 133.
[2] Ibid, vol. xxxiv, p 153

Mr. C. W. CATHCART demonstrated a Portable Stretcher adaptable to the Trendelenburg position.

Dr. G. H. MELVILLE DUNLOP and Dr. STUART MCDONALD showed a Liver from a case of Congenital Obliteration of the Bile-ducts.

Mr. F. M. CAIRD read a paper entitled, "Gastro-enterostomy—20 Cases performed for Intrinsic Stenosis and Tumour of the Pylorus." In this communication attention was drawn to the similarity between the symptoms and indications requiring gastrostomy and gastro-enterostomy. When there were difficulty in the onward passage of food, vomiting, progressive emaciation, anæmia, and subnormal temperature the operation could not be withheld long without incurring grave risk. It had been objected that gastro-enterostomy as practised in cases of malignant disease was an operation of grave risk, that it did not at all prolong the patient's life, and was of doubtful value. This view was controverted and it was maintained that even were life not prolonged the patients at least did not die from starvation, had less discomfort and pain, and did not of necessity face an ordeal of high mortality. It had been found a matter of experience, indeed, that as a result of the operation there was such a great gain in weight and bodily health that even in undoubtedly malignant cases there might arise a question as to the diagnosis. Moreover, in many of the cases the tumour had entirely disappeared. Of the 21 cases 20 were recommended as cancer, one was said to be innocent, due to gastric ulcer, and proved to be so. In every case save one a palpable tumour could be felt and in all it was found at operation. The chief symptoms were vomiting, emaciation, little or no free hydrochloric acid after a test meal, and other associated signs. Mr. Caird favoured the retro-colic operation of von Hacher but could not be certain that it made much difference whether the anterior or posterior method were used or whether the food current were isoperistaltic or antiperistaltic. It was largely a matter of convenience depending on the amount of disease and the mobility of the gastric organ, but he rather favoured a posterior gastro-jejunostomy as close to the duodenum as convenient, reserving the anterior operation for the more complicated cases. No special preparation of the patient was advocated prior to operation. The stomach was not washed out when the patient was unaccustomed to lavage or very weak on account of the tendency to syncope and prostration. After operation the patient received teaspoonfuls of warm water and milk at night if the general condition were good. A small dose of morphine was given for restlessness or pain. On the following morning, if there were eructations, tendency to vomit, sickness, or a rising pulse, the stomach was washed out. The great value of this after-treatment in all cases of gastric surgery was indicated. It frequently checked sickness at once and always did good, although here again the operator had to be prepared for an occasional dangerous syncope. Attention was drawn to the character, source, and quantity of the material evacuated. If the pulse did not fall after washing out then about 30 ounces of saline solution were transfused and always with benefit. Lavage and transfusion played a great rôle in after-treatment and might be judiciously repeated. Among the 21 cases four were fatal. The symptoms, causes, and treatment of the *circulus vitiosus* were discussed but no example of this condition had occurred. One male patient died from pleurisy, broncho-pneumonia, and congestion of the kidneys; the abdomen and field of operation were found to be normal. One woman died within 48 hours apparently from sheer weakness and another died from leakage. The disease had been so far advanced that the stitches were unfortunately planted in diseased tissue. The fourth was a case of peritonitis, probably due to aerial infection. The symptoms were very obscure and at the *sectio* there was found a purulent layer between the anterior parietal peritoneum and the anterior aspect of the omentum. The wound and field of operation were intact and healthy. Of the 17 patients who survived the operation six were known to be dead; three died from extension of the disease, two from sudden cardiac failure, and one from phthisis. Eight patients were alive after periods varying from six years, two years, and for less periods. Three had been lost sight of and probably were dead. At the time of operation all the patients were extremely emaciated. Thereafter they gained flesh rapidly and in many the tumour seemed to vanish and was no longer palpable. One case operated on in 1896 had been re-opened for a ventral hernia at the cicatrix and no trace of tumour or glands could be discovered. A second patient operated on in 1900 had also been subjected to a second laparotomy on account of the appearance of a few nodules on the cicatrix. The abdomen was found to be healthy. The tumours had almost gone; the nodules showed typical carcinomatous structure. The question might be raised whether these cases, which had survived say six months, were really cases of malignant disease after all. There could be no doubt that the diagnosis between simple inflammatory hyperplasias which simulated cancer and true cancer was extremely difficult, yet it would be extraordinary were able physicians so frequently in error. Again, the cases of slow-growing gastric carcinoma reported by Strüdel and others must be remembered, where after an exploratory laparotomy alone and closure of the abdomen the patient survived for several years. The great and rapid improvement in the health of all the above patients, however, could only be ascribed to the gastro-jejunostomy and not to the mere exploration and it offered strong encouragement to give the patient at least the advantage of a probable palliation and not to relegate him to the class of hopeless incurables.—Professor J. CHIENE and Mr. ALEXIS THOMSON took part in the discussion which followed.

Dr. G. LOVELL GULLAND read a paper on Cyto-diagnosis of Pleural Effusions. He stated that there were several varieties of pleural effusion, such as empyema, where an examination of the cells in the fluid was unnecessary, the organisms which caused its production being alone important. In serous effusions, however, the cells were of importance. Pleurisy was one of the commonest of acute chest affections and for many years it had been a matter of discussion whether the common acute serous pleurisy was rheumatic, tuberculous, "idiopathic," or due to acute infection. At one time all serous pleurisies were considered to be "rheumatic," at another idiopathic, and more recently the tendency to regard them all as tuberculous had been steadily growing. The immediate treatment necessarily differed according as one regarded a pleurisy as tuberculous or as idiopathic. A certain proportion of cases did not come into consideration—e.g., those in which a pleurisy supervened in the course of phthisis already diagnosed. There were many cases, however, where the lungs gave no help and where the pleurisy occurred in apparently healthy individuals. Here all the ordinary means of diagnosis might be exhausted without a decision as to the nature of the case being arrived at. The case might be really tuberculous, but the physical signs might be so slight as to pass unnoticed, and if the pleura of the more seriously diseased lung were attacked the effusion might conceal the disease by relaxing the lung or limiting the movements of the affected side so as to weaken the breathing. On the other hand, bronchial breathing and other auscultatory signs might be caused by the effusion itself and could not be referred to a pre-existing tuberculosis. For similar reasons tubercle bacilli might be sought for in vain in the sputum. Either there was no sputum or what there was came from the unaffected lung or from the trachea and bronchi and not from the relaxed lung. The injection of tuberculin for diagnostic purposes was also useless, for in almost all such cases the patients suffered from pyrexia. The sero-diagnosis of tubercle had so many technical and other difficulties that for practical purposes it was useless. The morphological examination of the blood did not give much help, as in slight and chronic cases the blood was practically normal, while in severe cases the leucocytosis might be high. The differential leucocyte count had not yielded any definite indication. In the absence of general indications the fluid drawn off by puncture fell to be examined. In fresh exudate organisms might be discovered either by culture or by the microscope, but the fluid was strongly bactericidal, and after some time the organisms ceased to be capable of cultivation though they might still be found in the fluid. It was true that in undoubtedly tuberculous cases it was only very rarely possible to demonstrate tubercle bacilli, either because very few bacilli were present, because they were destroyed or rendered incapable of growth by the fluid, or because the effusion was due to toxins rather than by the organism itself. In examining the cells in the exudate the methods were simple. The syringe was to be sterilised, by boiling by preference, and it must hold enough fluid to allow of its being centrifuged. If the cells were numerous in the fluid cover-glass preparations might be made directly and without using the centrifuge. Dr. Gulland generally fixed the films by his formalin-alcohol method. The tri-acid stain was not very serviceable but eosin and methylene blue and Jenner's stain had proved of the greatest use To show the granules in the polymorphonuclear cells or other changes Sudan followed by hæmatoxylin when fat was in question or iodine when glycogen had to be looked for had to be employed. The cells found in exudates might be classed according as they were derived from the blood or from the tissues. Red blood-corpuscles and leucocytes were, of course, present; also polymorphonuclear neutrophiles and the lymphocytes of various sizes. Basophile leucocytes were occasionally met with but eosinophiles were almost never seen. The red corpuscles showed no change of importance. The polymorphonuclear neutrophiles might resemble exactly those seen in the blood and usually did so in fresh effusions, but in older effusions degenerative changes were present in such cells. The cell body in such might undergo a simple dissolution, so rendering the granules free in the fluid, or it might undergo a fatty degeneration. The latter was very rarely seen in cells circulating in the blood but was fairly common in exudates. Glycogenic degeneration of the cell body was also more frequently observed in such exudates than in the blood. The nucleus of the polymorphonuclear neutrophiles might simply lose its power of taking up basic stains and might look faintly coloured. Most frequently, however, it lost the intranuclear network and stained deeply and homogeneously. The lobes also often separated one from another and broke up into fragments, each taking a part of the cell body with it, or the nucleus as a whole ran together into a ball and stained homogeneously. Such deeply stained nuclei had been mistaken for nucleated red corpuscles. The lymphocytes usually exactly resembled those of the blood and did not appear to degenerate nearly so frequently as did the polymorphonuclear cells. In simple effusions the cells were derived from the endothelial surface of the pleura. These sometimes occurred in clumps but more often they were single. They were larger than leucocytes usually, had a round or oval nucleus and a large cell body with a regular though more frequently a ragged outline. Fat droplets sometimes were found in the cell body. As regards tuberculous effusions the description differed according to whether the effusion was examined during the first three days or later. At first the cells were mainly polymorphonuclear, but by the third day these had largely disappeared and were replaced by lymphocytes In an established tuberculous pleurisy the microscope showed lymphocytes, red blood corpuscles, a few polymorphs in some cases and sometimes a very few endothelial cells. The lymphocytes ought to be at least half of the true cellular elements, while in most cases they reached four-fifths or even more. Dr. Gulland had drawn attention to the degenerative changes in other cells which caused them to look like lymphocytes because of the great importance which a true lymphocytic effusion had. He had seen effusions in which the degenerated polymorphs which simulate lymphocytes were at least as numerous as the unaltered polymorphs and so it would have been easy to come to an erroneous conclusion as to the nature of the case. The small number of endothelial cells present was generally explained by assuming that the exudation rapidly covered the pleural surface in those cases. As to effusions due to the pneumococcus and streptococcus, these organisms, and probably all others which could cause purulent effusion, had when the effusion was in the serous stage the same result—a great preponderance of polymorphonuclears, unaltered or degenerated, as the case might be, and often numerous endothelial cells, fresh or degenerated. Red corpuscles might also be present. The relations between polymorphs and endothelial cells varied greatly in different cases; the more acute the case and the more likely to go on to empyema the more polymorphs would, as a rule, be present As regarded œdematous effusions, whether such arose from heart or kidney, the cells were almost always very few in number and were mainly endothelial in type. In cases where a pulmonary apoplexy occurred in a lung the pleura of which already contained fluid polymorphs appeared in the fluid. Dr. Gulland then passed on to speak of malignant pleurisies. As a rule cells of the malignant growth would be present in the fluid, often in large numbers. They were frequently swollen and œdematous and they presented abnormalities in the nucleus. They were often fattily degenerated. A certain proportion of polymorphs was present. Dr. Gulland had found cyto-diagnosis distinctly useful and by its aid he had been able to free some people from the suspicion of tubercle, though, unfortunately, he had had to condemn others and he hoped that it might prove of equal value to observers when associated with minute investigations in other directions.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

Lead-poisoning.—Milch Cows and the Tuberculin Test.—Inspection of Dairy Sheds.

A MEETING of this section was held on April 25th, Dr. NINIAN FALKINER, the President, being in the chair.

Dr. F. O. MARTLEY, honorary secretary of the section, read a communication from Dr. R. B. McVittie on a case of Lead-poisoning. The patient, a man, aged 58 years, after three months' residence in a new house began to complain of general malaise, muscular weakness, and abdominal pains. Two months later he suffered from vomiting, constipation, and some loss of power in his hands. As he had no teeth the gums showed no lead line. The water-supply came from two wells situated above the house and was conveyed in iron pipes which ended in a few feet of leaden pipe to which the tap was attached. Water taken from the tap was found to contain 1·67 grains of lead per gallon, that from the wells was pure, soft, and slightly peaty. Since discontinuing the tap water he had become completely well Of all the household he alone was affected; this was probably due to his age and to his having lived for some time both in India and in Burma.—Sir CHARLES A. CAMERON said that the case was of interest from the exceptionally large amount of lead present, this being greater than was usually found except in acid solutions. The water-pipes used in Dublin consisted of an alloy of lead, 96 5 per cent., and tin, 3 5 per cent. This had after years of trial, been found to resist the solvent action of water.—Dr. DE LISLE of New Zealand, a visitor, said that in New Zealand lead-poisoning was practically unknown. He had seen two cases only and they were in painters. He ascribed the immunity to the hardness of the drinking-water in the towns. Before he settled in New Zealand he lived in Sydney and whilst lying ill with typhoid fever in the General Hospital of that city he saw many cases, the victims being heavy beer-drinkers whose liquor had been contaminated with lead from the leaden pipes of the beer-machines. The drunkards of Sydney were beer-drinkers; the moderate drinkers took whisky.—The PRESIDENT made a reference to a meeting of the section in 1873, when Dr. O'Carroll brought the subject of lead-poisoning from hair-dyes under notice.

Professor E. J McWEENEY read a paper on the Infectivity of the Milk of Cows which Reacted to the Tuberculin Test but were not Clinically Tuberculous. He said that it was a problem whether the milk of cows that reacted to the tuberculin test should be permitted to be sold for human consumption. He commenced his experiments by trying to learn the percentage of milch cows that reacted to the test. For this purpose he examined a herd of cattle numbering between 80 and 100 animals that was kept under hygienic conditions very much superior to those of ordinary herds, and of these cattle kept under the most favourable conditions 50 per cent. reacted positively to the tuberculin test. He afterwards, in the south of Ireland, examined a herd of cattle that was not kept under the same favourable conditions, and of these from 80 to 90 per cent. reacted to the tuberculin test. To decide that the milk of animals that reacted to the test was unfit for food would be to cut off the milk supply and would be impracticable Some of the animals vigorously reacted to the toxin, the temperature rising from normal to 105°, 106°, and even to 108° F. Strange as it might appear, he found the infection to be inversely proportionate to the extent of the tuberculous lesion, the possible explanation of which might be that the animals which were clinically tuberculous had had their blood immunised by the toxin already in their bodies and injected tuberculin produced a slight, if any, reaction. In the animals in which violent reaction took place he found not more than one or two caseous glands, most commonly in the posterior mediastinum. All these statements were based on post-mortem experiments, for every animal which he experimented on was afterwards killed. Animals that had encysted little masses of tubercle gave milk in which tubercle bacilli could not be found. He then described a series of experiments instituted for the purpose of testing the effects of the milk of cows giving a reaction to tuberculin but not clinically tuberculous. It must be remembered that "acid-fast rods" simulated bacilli and had been mistaken for them. Almost identical experiments, but conducted on a much larger scale, were carried out in Berlin by Perstatay who fed young animals, calves and pigs, on the milk of cows which were tuberculous but in which the disease was not clinically demonstrable. The calves were fed for two months and the pigs for seven months on the milk and in not a single instance did tubercle develop. The milk was perfectly innocuous. On the other hand, the disease was in a very infectious form when the cow's udder was infected, for the least amount of tubercle in the udder made the milk poisonous. Dr. Bang of Copenhagen gave a litre of milk drawn from a cow with a tuberculous udder to a pig and the animal died in a short time as if poisoned. The percentage of tuberculous cows whose udders were tuberculous was calculated to vary from 2 to 4 per cent. Professor McWeeney said that he had never come across a case of infected udder, but there should be no difficulty in recognising it and any educated veterinarian should be equal to the task. So far as his experience went he considered bovine tubercle to be capable of infecting the human being.

Sir **Charles Cameron** read a paper on the Inspection of Dairy Sheds. He thought that dairy inspectors should not be satisfied with the sterilisation of the milk and other matters appertaining to the hygiene of the cowsheds and that the dairy should be looked after. Inspectors in rural districts were not at all so careful as were those in Dublin, neither were the rural cowsheds and attendants as clean as the city sheds and attendants. The recent Vice-regal Sanitary Commission declared that the cows in the city dairy-yards were much better fed than were those in the rural districts. The Dublin cows were sent to grass for seven months of the year; their milk contained 14 per cent. of solids as against 12 per cent. in the country. A veterinary surgeon examined their udders regularly during the winter season and the personal cleanliness of the attendants was ensured by a by-law which made dirty hands punishable by a fine and during the last year 40 milkers were fined for having their hands dirty.—Professor **McWeeney** said that a codification of the sanitary laws was a necessity; as things were a whole library of legal books was wanted to find out the law of sanitation. Sterilisation of milk was out of the question, it made ordinary milk unsightly and unpalatable and spores resisted boiling for three hours under a pressure of two atmospheres. Pasteurisation killed typhoid germs at a temperature of 140° F., and at 190° it killed the tubercle bacilli; no creamery should be allowed to vend milk until it had been properly pasteurised. As for the Dublin dairy-yards, he considered them to be a disgrace to civilisation; they were kept in an intolerably filthy state and, as for the attendants, he thought that if they had the German sanitary law in force in Dublin some 90 per cent of the milkers would be arrested and forcibly washed. There could be no proper supervision of dairies without a bacteriologist; a veterinarian could not make an exhaustive microscopical examination of milk or perform the necessary biological experiments.

Laryngological Society of London.—A meeting of this society was held on May 2nd, Mr. E. Cresswell Baber, the President, being in the chair.—Dr. A. Bronner showed macroscopical and microscopical specimens of a large Papilloma of the Left Maxillary Antrum which had caused destruction of the bone and was accompanied by an offensive discharge. It had been twice removed with a snare and the second time without recurrence.—Dr. J. Walker Downie showed (1) a specimen of Sarcoma of the Right Tonsil from a woman, aged 58 years, which was enucleated in September, 1890, and did not recur until after October, 1901; (2) a specimen from a man, aged 33 years, consisting of the Soft Palate, Fauces, Pharynx, Larynx, and Gullet, the seat of an Extensive Round-celled Sarcoma; (3) a large Fibrous Growth (removed November, 1892) from the Naso-pharynx of a boy, aged 11 years, who a year later developed symptoms of sarcoma of the left maxillary antrum; and (4) a large Fibrous Growth (removed Feb. 6th, 1901), from the Naso-pharynx of a boy, aged 14 years, followed by continued improvement in health, and with no local recurrence.—Dr. J. Donelan showed (1) a case of Laryngeal Stenosis in a man, aged 50 years, resulting from a large syphilitic ulcer of the left side of the larynx; and (2) a case of Syphilitic Contraction of the Posterior Pillars of the Fauces in a man, aged 44 years.—Dr. H. Tilley showed a case of Complete Occlusion of the Right Nasal Vestibule in a man, aged 32 years, following the insertion of a strong styptic for the arrest of epistaxis. The septum was deflected to the right, and Dr. Tilley said that he proposed to remove the scar tissue and at the same time to perform Ash's operation on the septum.—Dr. H. L. Lack showed the following cases. 1. A case of great Symmetrical Thickening of the Upper and Anterior Part of the Nasal Septum in a man, aged 33 years, who had been under constant treatment for the past 12 years for nasal obstruction. It had been cut away and cauterised many times, but had always recurred. 2. A case of Inherited Syphilis of the Nose, Pharynx, and Larynx, with Complete Occlusion of the Anterior Nares in a boy. The appearances in the pharynx and larynx closely simulated lupus but the ulceration which at first had existed about the right anterior nares had healed under iodide of potassium, leaving complete atresia. The left nostril was already occluded.—Dr. J. W. Bond showed a case of large Laryngeal Growth in a woman who had suffered from huskiness of the voice for 10 months. There was no history, or sign, or symptom of either tuberculosis or syphilis.—Dr. StClair Thomson showed a case of Glosso-labial Laryngeal Paralysis with Complete Paralysis of one cord and Adductor Paralysis of the other.—Dr. E. Law showed a case of Excrescences or Incrustations or Chalky Deposits low down in the Trachea.—Mr. R. Lake showed a case of Tuberculosis of the Larynx occurring in a man, aged 30 years, in which the epiglottis had been removed by means of the galvano-cautery snare. The stump had healed quite satisfactorily.—Dr. L. H. Pegler showed a case of Geographical Tongue occurring in a boy, aged 14 years.—Mr. F. H. Tod showed a case of Syphilitic Necrosis of the Intra-nasal Structures.—Mr. E. B. Waggett showed a case of Cystic Adenoma of the Pyramidal Lobe of the Thyroid Gland.

British Gynæcological Society.—A meeting of this society was held on May 8th, Dr. Heywood Smith, one of the Vice-Presidents, being in the chair.—Professor Alfred Smith exhibited a Bilateral Intraligamentary Fibromyoma of 10 pounds Weight in Advanced Mucoid Degeneration removed on April 16th, 1902, from a woman who till last November had been in good health.—Dr. Bedford Fenwick showed a similar specimen of which the lower part on the right side had been embedded in the broad ligament; the upper part on the left had extended right under the ribs and was in extreme mucoid degeneration.—After the exhibitors had replied to some remarks made by Dr. Heywood Smith, Dr. J. J. Macan, Dr. H. Macnaughton-Jones, and Dr. Richard T. Smith, Dr. Macnaughton-Jones related two cases of Absence of the Internal Genitalia. The patient in the first case was a girl, aged eight and a half years. Abdominal symptoms led to recto-abdominal examination, as even after consultation with a physician no definite diagnosis could be made. A soft sausage-shaped tumour was felt by the rectum but no uterus could be detected. On operation the tumour proved to be a sacculated sigmoid, doubled down on the rectum and containing fæces, but the appendix, six inches long, was bound down to the floor of the pelvis and contained pus. There was no uterus or any adnexa. The appendix, which was ruptured in detaching it, was removed, and in spite of a fæcal discharge from the abdominal wound from the fifth to the eighth day and an intercurrent attack of cystitis the child made a good recovery. In the second case the patient was a woman, aged 32 years, who had suffered from persistent primary amenorrhœa, with headaches and molimina, from the age of 18 years. Sexual instincts seemed to be present as there had been a question of marriage, but the absence of the catamenia and uncertainty whether the marriage could take place had led to much mental depression and deterioration of health. The labia, clitoris, and urethral orifice were present but there was no vagina, and bimanual recto-abdominal and recto-vesical examination proved the absence of the uterus, ovaries, and tubes, nor could any trace of such, or of a vagina, be found by exploration of an incision in the middle line into the fibro-muscular tissue between the bladder and the rectum. The patient's mental depression was much improved by the removal of all uncertainty as to her position. Her headaches turned out to be dependent on eye-strain due to hyperopic astigmatism which was completely relieved.—Dr. C H F. Routh, Professor A. Smith, Dr. S. J. Aarons, and Dr. Heywood Smith instanced similar cases and concurred that absence of the internal genitalia was not quite exceptional in women who were well developed externally and who had normal sexual instinct.—Dr. Macnaughton-Jones, in reply, spoke of the futility of unduly delaying diagnosis and continuing ordinary treatment in persistent primary amenorrhœa and of the importance of all cases being recorded in which the genitalia were absent.—Dr. Fenwick read a paper on Fifty Laparotomies which with 35 simple operations for the removal of ovarian cysts or uterine fibroids were the only cases in which he had opened the abdominal cavity from above during the last 16 months. These 50 were all more or less difficult operations and included the only fatal results he had met with in his abdominal sections for nearly three and a half years, two deaths after hysterectomy for malignant disease and for degenerated fibroids of the uterus both by a singular coincidence occurring in the first week of this month, but neither due, save indirectly, to the operation, the patients sinking from heart failure several days afterwards The frequency with which fatty degeneration was caused by abdominal tumours, to which he had drawn attention some 15 years ago, seemed now to be generally admitted. The 50 operations included 24 for ovarian growths, of which five were malignant, the disease being removed in three, but in the other two it was too far advanced for extirpation; 14 for fibroid growths, in connexion with which he laid much stress on the importance of degeneration as an indication for interference and of pain in previously painless cases as a symptom of inflammatory change consequent on such degeneration; six for bilateral and three for unilateral (left) pyosalpinx, all associated with great and increasing pain, profuse menorrhagia, and marked loss of flesh and strength, and by vast improvement after operation; and one each for malignant uterine disease, extra-uterine fœtation, and abdominal hernia due to a fall down a flight of stairs after a previous abdominal section.—Dr. J. A. Mansell Moullin said that among 173 abdominal operations at the Hospital for Women, Soho-square, London, during last year they had had only eight deaths, of which seven followed operations not properly gynæcological, 57 ovariotomies, 21 hysterectomies, and five myomectomies without any mortality, the single fatal case being one of 22 oöphorectomies These figures showed the position of special gynæcological work at the present day and would compare not unfavourably with the results of such work in general hospitals.—After some discussion by Dr. R T Smith, Professor A. Smith, Dr. Macnaughton-Jones, and Dr Heywood Smith, Dr. Fenwick replied.

WEST KENT MEDICO CHIRURGICAL SOCIETY.—The seventh meeting of the forty-sixth session of this society was held on May 2nd.—The President, Dr. T. C Meggison, delivered a presidential address on Migraine. After some preliminary remarks the speaker defined migraine or hemicrania and reviewed the different phenomena which go to make up an attack. The premonitory symptoms were discussed in detail, particularly those affecting the eyes. He remarked on the fact that many persons were first attacked in the early hours of the morning and also how impossible it was for the physician to appreciate the suffering on an ordinary professional visit. The situation and character of the pain, the gradual increase in intensity, the alternation from one side to the other, the sickness and prostration, and the aggravation of the symptoms by light, noise, &c., were rapidly passed in review He noted the alteration in pulse and temperature and described in detail the three principal varieties. He combated the theory of eye-strain being the sole cause and stated that he had long been of the opinion that there was some other influence at work. The history of his own cases showed a decided tendency to transmit the complaint. He considered that there was a great deal of evidence to show that migraine was due to toxins formed in the intestine but only absorbed into the system at certain times, such as during menstruation, after a shock, prolonged fatigue, or excitement. Acting on this theory he had tried washing out the system by large draughts of water with some measure of success but the disadvantages were obvious. Washing out the intestines by large enemata had been of benefit in various cases, though many had suffered from headache during the process. The result was certainly encouraging. For some time he had tried giving an enema whenever an attack seemed imminent with the most gratifying result, the patient generally experiencing complete relief, though sometimes the attack was merely shortened. Various patients had been treated in this way with the same benefit. In other cases washing out had been first performed and then the bowels had been kept clear by mild laxatives with decided success. From these results he was of opinion that migraine did not depend on a single cause but that in all cases there were two or three factors at work and that most probably auto-intoxication was one.—After the address an enjoyable smoking-concert was held. Mr R. F. Tyler presided at the piano and songs, recitations, and violin selections were contributed by Dr. James Donelan, Dr. R. E. Scholefield, Dr. T. E. White, Mr. R. V. Donnellan, Dr. F. S. Toogood, Dr. H. Bowen Williams, Mr. Samuel Masters, and Mr. Wilson James.—The annual dinner of the society will be held at the Café Monico on Thursday, June 19th.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on May 9th, Dr. Arthur T. Davies, the President, being in the chair.—Dr Leslie Durno read notes of two cases of Pemphigus Neonatorum. The mother of the first child suffered from moist eczema at the time of her delivery. Her child developed vesicles on the third night. These quickly multiplied until the skin, save only that of the palms of the hands and soles of the feet, was affected, yet the constitutional disturbance was slight. Healing took place in 14 days except in those parts kept moist by the urine and fæces. The rash of the second child began on the sixth night and was severe, closing the eyelids and producing a good deal of general disturbance.—Dr. J. R. T. Conner thought that such cases were impetigo contagiosa and not true pemphigus—that they were the product of staphylococcic infection and were curable by antiseptics.—Mr. W. Campbell M'Donnell related a case of Septic Thrombosis in a pregnant woman, a multipara, aged 28 years, who shivered daily for a fortnight before her delivery She had pain in her legs but was not medically attended before or after delivery. The day after delivery there was an inflammatory swelling at the back of the left thigh which on being opened later proved to be an abscess. On the fourth day of lying-in there was a supposed dislocation of the wrist, but this also proved to be an abscess. The pus was let out. The joint was ultimately disorganised. There was a large discharge of pus in the urine on the fourteenth day and hæmaturia till the end. Septic pneumonia occurred later and she died on the thirty-sixth day. There was no post-mortem examination. The speaker held the pyæmia to have resulted from septic thrombosis in the varicose veins of the leg—Dr Conner read notes of a case of Injury to the Hip in a man, aged 73 years, from a fall from a bicycle. The injury at first gave no signs of fracture or dislocation beyond the patient's inability to walk. Blood pigment appeared over the hip and the lower abdomen He was in bed for a month. After that time he tried to walk but was unable to do so. Three months after the injury half an inch of shortening of the leg was noticed Dr Conner explained this shortening by the observation of the late Mr. Jones that blows on the hip might produce shortening by interfering with the blood-supply to the bone to such an extent that absorption of the femoral neck resulted.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 16th, Mr. E. C Kingdon, the President, being in the chair.—Mr. R. Wood (Ilkeston) showed a case of Lupus Vulgaris which 10 years ago was treated with injections of Koch's tuberculin. The disease was arrested for a time but remained uncured.—Dr. W. E. Tresidder showed a case of Epithelioma of the Cervix Uteri which had been treated with the x rays, under which all signs of the disease had disappeared. A microscopic section of a portion of the growth taken before treatment was started confirmed the diagnosis—The case was discussed by the President, Mr. A. R. Anderson, Dr F. H Jacob, and Dr. J. S. Bolton.—Mr. Anderson read a paper entitled, "The Surgical Treatment of Gastric Ulcer." After some observations on the question of diagnosis Mr. Anderson confined his remarks to the treatment of (1) non-perforated ulcers and (2) hæmorrhage. Statistics were put forward showing the probable mortality from ulceration and hæmorrhage under medical treatment, and whilst advocating preliminary treatment by medical measures in all cases it was urged that earlier recourse should be had to surgical operation. In regard to the question of hæmorrhage the anatomy of the arterial supply of the stomach was first demonstrated and then the surgical measures for the arrest of bleeding were described.—The lateness of the hour precluded discussion of this valuable paper.

BIRKENHEAD MEDICAL SOCIETY.—The annual meeting of the above society was held on May 9th, Dr. J. Pinkerton, the President, being in the chair.—Mr. S. H. N. Harrington showed a patient with a Displacement of the Heart. The apex beat was in the seventh interspace, midway between the posterior axillary line and the spinal column. There was a complete absence of cardiac dulness in the front of the chest. There was no history of pleurisy or of overstrain to account for the displacement.—The President, Dr. J. Lambert, Mr. H. Laird Pearson, Dr. J. H. Dixon, and Dr. E. H. Brien commented upon the case.—The President showed the following specimens: 1. A small Calculus removed from a child, aged five years, during the operation of circumcision. The calculus was lodged between the prepuce and the glans penis. 2. The Stomach of an infant, aged six weeks, the pyloric orifice of which was so much contracted and thickened that a probe could only be passed through it by exercising considerable pressure. During life the child had vomited almost all food.—Dr. White showed a specimen of Imperfect Closure of the Foramen Ovale.—The Secretary showed a similar specimen.—The following officers and members of committee were elected for the ensuing year:—President: Mr. Pearson. Vice-president: Dr. Brien. Librarian: Mr. S. Wilkinson. Treasurer: Dr. W. R. Floyd. Secretary: Mr. J. H. Fardon. Committee: Dr. W. R. Dalzell, Mr. A. W. Pierce, Dr. R. O. Morris, Mr. W. Johnstone, and Dr. W. Leask.

BRITISH ELECTRO-THERAPEUTIC SOCIETY.—A special meeting of this society was held on May 2nd, Dr. W. S. Hedley, the President, being in the chair.—The motion to admit registered medical students as associates was negatived by the members present.—The ordinary meeting then followed.—The adjourned discussion on Dr. J. H. Sequeira's paper on the Finsen Treatment of Lupus, Rodent Ulcer, &c., was then opened by the President.—The following members took part in the discussion: Dr. H. Lewis Jones, Mr. J. F. Hall-Edwards, Dr. G. H. Graham, Dr. Horace Manders, Dr. F. Harrison Low, Mr. E. W. H. Shenton, Dr. H. McClure, and Mr. Chisholm Williams.—The general opinion of the speakers was strongly in favour of the Finsen and other allied forms of treatment for the conditions in question.—Dr. Sequeira replied.—It has been decided to hold the provincial meeting at Manchester on July 30th.

SOCIETY OF ANÆSTHETISTS.—A meeting of this society was held on May 2nd, Mr. Walter Tyrrell, the President, being in the chair.—Dr. Joseph Blumfeld read a communication entitled, "Some Points concerning Complete Relaxation of the Abdominal Muscles under Anæsthetics."—In the discussion that followed the President, Dr. H. Low, Dr. Dudley W. Buxton, and Dr. Harvey Hilliard took part.—Dr. G. B. Flux submitted a further communication on the Use and Structure of his Open Stopcock.—Dr. W. Millward showed a Modification of Clover's Inhaler designed for the purpose of administering ether or chloroform singly or together.

HEALTH OF EXETER.—Dr. J. Woodman, the medical officer of health of Exeter, reports that during 1901 the births numbered 1084, this being equal to 23·1 per 1000. The total number of deaths registered was 830, this being equal to a corrected death-rate of 16·4 per 1000. The infant mortality under one year was 152 per 1000 births. 533 cases of scarlet fever occurred during the year; 340 of these patients were removed to the sanatorium where four of them died; the remaining 193 were treated at their own homes and six died. Two cases of small-pox, 41 cases of enteric fever, 40 cases of diphtheria, and three cases of puerperal fever were notified.

Reviews and Notices of Books.

The Principles of Pathological Histology. By HARVEY R. GAYLORD, M.D., Professor of Surgical Pathology in the University of Buffalo, attending Surgeon to the Erie County Hospital, Buffalo, N.Y.; and LUDWIG ASCHOFF, M.D., Professor and First Assistant in the Pathological Institute of the University of Göttingen. With an Introductory Note by WILLIAM H. WELCH, M.D., Professor of Pathology in the Medical School of the Johns Hopkins University, Baltimore, M.D. Illustrated with 81 Engravings in the Text and 40 full-page Plates. London: Henry Kimpton. 1902. Pp. 359. Price 5s. 6d.

THIS work is intended to supplement the regular courses in pathological histology and to lead the student to the application of such knowledge in practice. The arrangements now made in all medical schools for the preparation of all microscopical specimens of various morbid conditions enable every student to obtain for himself an excellent collection of this nature. This, however, is not sufficient; he must be able to interpret the appearance of actual objects seen through the microscope. A book to confer this ability must present the histology of the various diseases as faithfully as the microscope itself. This has been one of the chief aims of the authors of this volume. Evidently no effort or expense has been spared in illustrating it and a most excellent publication is the result. We are informed that special apparatus was devised for the optical and photo-micrographic work and the negatives thus secured have been reproduced by the heliotype process. The plates are some of the best that we have seen in a text-book of this nature. The tricolour photo-micrographs are particularly successful.

The book is divided into three parts. In Part I. are fou the most trustworthy methods for preparing tissues for mic scopical examination. It is so arranged as to be equally us to the student and to the practitioner. This part o work is not overcrowded with descriptions of numerou cesses which have been from time to time introduce only those have been selected which are comparatively s and which yield the best results.

Attention is called to the "simplicity" of the techni the freezing microtome as contrasted with the "difficu of the paraffin or celloidin method. We cannot alto agree with the authors in this respect. It is true such an excellent, although expensive, instru "Becker freezing microtome" be employed results may be obtained, but if the ordin microtome is used the student will find difficulty in obtaining satisfactory sections f morbid specimens, whereas with tissues embed paraffin or celloidin, although the time required for pre ing the tissues is considerably longer, there will b larger proportion of successful results.

The student will have no difficulty in following the dir tions given for staining the preparations. The description the "special methods" will be found to be especially useful these include the processes for staining sections of th central nervous system. Great advances have been made i this direction during recent years and the methods o Weigert and Mallory have proved of immense value i differentiating the tissue elements of the brain and the spina cord.

Part II. includes the principal portion of the work an deals with the Pathological Histology of Organs.

The sections describing the morbid changes which ma occur are arranged on a uniform plan. A brief definition i first given of the condition about to be described. The directions are given as to how the tissues of the organ unde that of an achondroplasic dwarf and the figure of Bes that of a myxœdematous dwarf. Achondroplasic workers in metal are represented on the Egyptian monuments, a circumstance which is interesting in connexion with the lameness and deformity of Hephaistos or Vulcan in classical mythology.

THE FOURTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

THE present rate of exchange makes it worth while for all those who propose to attend the Madrid meeting of the International Medical Congress to pay their subscriptions at once as the value of the peseta varies from time to time and it is now low. The necessary forms of application for membership can be obtained from the honorary secretaries of the National Committee for Great Britain and Ireland—viz., Mr. D'Arcy Power, 10A, Chandos-street, Cavendish-square, London, W. and Dr. P. Horton-Smith, 15, Upper Brook-street, Grosvenor-square, W., who are prepared to transmit the subscriptions to Madrid and to supply receipts and cards of membership as soon as they are issued, in return for a postal order of £1 from each member. Ladies if they accompany a member will pay 6*s.* 8*d.* for their tickets, which sum is said to entitle them to reductions of fare on the Spanish railways (probably a useless concession for English travellers who take through tickets) and will give them admission to the various fêtes held during the congress.

THE TOPOGRAPHY OF THE CORTICAL DEGENERATIONS IN GENERAL PARALYSIS OF THE INSANE, WITH SPECIAL REFERENCE TO FLECHSIG'S ASSOCIATION-CENTRES.

AN important research by Professor Karl Schaffer of Budapest on the topography of the cortical degenerations in general paralysis of the insane in relation to Flechsig's association-centres of the brain is recorded in a recent issue of the *Neurologisches Centralblatt* (No. 2, 1902). A detailed microscopical investigation was made of the entire brains of three patients who had died from general paralysis, tabetic symptoms having been also present in one of the three cases. Serial sections of the entire brain (cerebral hemispheres, brain-stem, and cerebellum) were made in the sagittal and horizontal planes and were stained with Wolter's modification of Weigert's method to determine the situation of degenerated medullated nerves. All three patients were typical examples of general paralysis with the characteristic symptoms of early dementia, grandiose delusions (megalomania), impairment of speech (dysarthria), and paralysis of pupillary and of facial movements, and they terminated in paralysis, coma, and death. Sagittal sections taken close to the mesial aspect of the cerebral hemisphere showed degenerations of medullated nerves, chiefly in the pre-frontal area (pre-genual and sub-rostral regions)—i.e., Flechsig's antero-mesial and supra-orbital association-centres, slightly around the lips of the calcarine fissure and moderately in the supra-callosal convolutions (gyrus fornicatus). Sections made in other planes showed various areas of degeneration. The degenerations are classed as "slight" and "marked" and their distributions are summarised as follows. (*a*) Slight degenerations: these were observed in the Rolandic convolutions and adjacent parts of the frontal gyri (kinæsthetic area) in the cuneo-lingual gyri which border the calcarine fissure (visual region) and in the lower temporal gyrus (*b*) Marked degenerations. These were observed in the pre-frontal lobe (polar and orbital regions), in the parietal lobe (superior and inferior gyri), in the ascending parietal convolution, in the insular and in the temporal convolutions. (*c*) An intermediate degree of degeneration was present in the occipital lobe. A special examination of the brain of the patient whose symptoms were complicated with tabes showed that slight degeneration was present in the ascending frontal convolution and adjacent parts of the frontal gyri, in the cuneus, in the first and last temporal convolutions, and in the nerve-tracks or bundles of the cornu Ammonis. Marked degeneration was present in the pre-frontal lobe, in the entire parietal lobe (including the ascending parietal convolution), in the insula, gyrus fornicatus, and second and third temporal convolutions. A comparison of these regions with the areas delineated by Flechsig in his classical work[1] as "association-centres" of the brain will show the close correspondence that exists between the two. Professor Schaffer concludes that his observations tend to support Flechsig's localisation of the association-centres of the brain, and that the morbid process (degeneration of medullated nerve-fibres) affects chiefly Flechsig's centres—viz., those in the pre-frontal, parietal, insular, and supra-callosal regions of the hemisphere. "The cortical degeneration in general paralysis is not an irregular, diffuse process, but, on the contrary, a regular, localised, selective morbid affection of the cortex." The research is of great importance and must naturally form the starting-point for further observations of similar nature to be made on other forms of insanity.

VACCINATION DIFFICULTIES.

IN THE LANCET of March 29th, p. 906, we referred to certain difficulties which had arisen between the Board of Guardians of Great Yarmouth and Dr. Henry Blake, the public vaccinator. Shortly the story was as follows. About the middle of March Dr Blake, in view of the approaching Easter holidays and the Yarmouth fair, thought that it would be well to have power to employ assistants as the work of vaccination and revaccination was growing very heavy. He therefore wrote to the Local Government Board and this body wrote to the guardians and recommended them to confer with Dr. Blake. However, at a meeting of the guardians held on March 18th the guardians refused to confer. A special meeting was then called on March 25th when it came out that Dr. Blake had asked the clerk to the board of guardians what he should do to get assistance. The clerk advised him to write to the Local Government Board. Only the clerk forgot to mention this to the guardians. Hence the talk about discourtesy to the board on the part of Dr. Blake which made the guardians refu confer with that gentleman after the meeting on the 1 Peace, however, now reigns and at the next meeting of guardians Mr. Cass is going to move that the board fi early date for consultation with Dr. Blake. This is all orthodox and ceremonious, no doubt, but epidemics will wait for ceremony and we should like to see some rapid method by which a public vaccinator could assistance in time of need than that which Dr. Blake to employ. Dr. Blake was invited to attend the meetin March 25th. Why could not the conference have been then and there? The whole matter could have been so in five minutes.

COEXISTENCE OF INFANTILE CEREBRAL PA PLEGIA AND INFANTILE SPINAL PARALYSIS

AT the meeting of the Société Médicale des Hôpitau Paris on March 7th M. Pierre Marie showed an interes case in which infantile cerebral paraplegia and infa spinal paralysis coexisted. The patient was a man, 34 years. At the age of six months he had convulsions from this time his paraplegia probably dated. The r lower limb was semi-flexed and adducted and c not be completely extended; the foot was in position of equinus. The knee-jerk was increased; plantar reflex was of the extensor type. All the symp consideration may be most advantageously treated and prepared for examination both in fresh and hardened specimens, and then the microscopical changes are fully described.

---

[1] Gehirn und Seele, 1895.

It is by no means easy to give a written account of histological appearances, but in this work the authors express themselves in terms which are easy to comprehend and they are assisted by an excellent series of reproductions of photo-micrographs. These have been carefully selected and the student will find the acquisition of a knowledge of morbid anatomy much facilitated by comparing these plates and the description that accompanies them with the specimens which he has himself prepared in the laboratories. We strongly disapprove of the substitution of plates and diagrams for actual specimens but a comprehension of what is seen through the microscope is much aided by reference to good illustrations, and in the work now before us both the letterpress and the engravings are all that can be desired. The above remarks are especially applicable to those organs of the body of which it is difficult to procure good microscopical specimens. For instance, sections of the digestive tract are not easily prepared; but the photographs reproduced on Plates XVI. and XVII. show admirably the microscopical changes associated with tuberculous ulcers in the intestine, "typhoid swelling of the intestine," aphthæ of the œsophagus, colitis cystica, and dysentery. The sections of bone, too, are instructive; they include rachitic rib, syphilis of the femur, and the normal ossification of a rib. The coloured plates are also beautifully reproduced. The colours in some instances appear rather too vivid but this is by no means a serious fault.

Part III. of the book contains a simple exposition of the optical problems with which the student should be familiar, and also some technical directions for those who wish to make attempts at photo-micrography.

The Foraminifera: an Introduction to the Study of the Protozoa. By FREDERICK CHAPMAN, A.L.S., F.R.M.S. London: Longmans, Green, and Co. 1902. Pp. 354, with 14 Plates and 42 Illustrations in the text. Price 9s. net.

THE title of Mr. Chapman's book is quite accurate but the sub-title which he has selected is by no means so. The book is not at all an "Introduction to the Study of the Protozoa," except, indeed, on the principle that in studying a particular group a beginning must be made somewhere. No general protozoan problems are discussed or even mentioned and the structure of the unicellular [illegible], as a whole, is barely treated. By an "intro[illegible]," we are led to expect something more than [illegible]ges which naturally deal with the protozoa as a [illegible] in the briefest fashion. Considered as a manual of [illegible]aminifera there is much to be said in favour of Mr. Chapman's volume and also something on the other side. It is chiefly with the illustrations that we find fault; they are numerous, it is true, but mostly coarse in execution. It would have been better if the numbers had been reduced and the excellence of those selected had been assured. We distinctly prefer few and well-executed drawings to the rude plenty with which this volume is provided.

As regards the book itself, the letterpress that is, Mr. Chapman is entitled to commendation. In the first place, the volume is not in any proper sense of the word a compilation. The author is one who has mainly devoted his scientific work to the elucidation of the foraminifera and we think it a wholesome state of affairs when a student writes upon the objects of his own particular study; it means enthusiasm and, in consequence, good work. Though dependent largely upon his own first-hand knowledge of this group of protozoa, Mr. Chapman by no means ignores his fellow-workers and forerunners in this branch of inquiry. Nearly 20 pages of bibliography are occupied with an enumeration of the titles of works upon these creatures, arranged in a way which has its uses; the list is partly chronological and partly divided into such heads as "Technical Preparation," "Biology," and so forth. These shelled protozoa are favourite objects of study to the mere microscropist, to him who merely wishes to examine beautiful forms without special interest in their structure, life-history, and range in time and space. Occurring in great abundance and variety, in the most diverse situations, it is natural that they should thus have been selected as objects of microscopical interest. Mr. Chapman, however, in no way panders to this, the more ignoble, side of microscopy. He forces upon the reader who needs taking in hand in this way a mass of valuable information. For the serious student he provides mainly an admirable *résumé* of the structural characters of the several families, genera, and even, at times, species. The vastness of the numbers renders any attempt at completeness in the enumeration of species clearly out of the question in a handbook of limited extent and large—perhaps rather too large—type. A judicious handling of "minion" might have allowed the author to be a little more comprehensive. However, we do not quarrel with him for any serious omissions. The matter treated seems to us to embrace all that there is to be said of importance respecting these foraminifera. They furnish many and very varied problems for our consideration, with some of which the author duly deals. The celebrated voyage of H.M.S. *Challenger*, concerning which Mr. Chapman often finds himself compelled to remark, and previous deep-sea exploring voyages, had led some naturalists to the idea that the "globigerina ooze" now falling in an impalpable rain on to the ocean bottom through tracts of thousands of miles was exactly comparable to the chalk of Dover and of Gris Nez. The obvious conclusion was therefore that the chalk, instead of being a deposit in shallow water, was in fact a deep-sea deposit. This clearly led to a reconsideration of a view which has oscillated greatly in the last few years. If an abyssal deposit of a previous period of the earth's history now forms a part of the solid ground upon which we walk it is plain that no belief can be held in the "permanence of the great oceans." Continents now divided by miles of water thousands of fathoms in depth might have been united in the closest embrace. It is true that the forms of foraminifera found in globigerina ooze on the one hand and in cretaceous chalk on the other are often identical, and that imbedded in this foraminiferal mass are the remains of such creatures as sea urchins which also present a great similarity in the two cases. But one fatal objection is the presence in the chalk and the absence from true deep-sea ooze of organisms which are in all probability creatures limited in their range to shallow waters and which are unfitted, or at least are not known, to live in abyssal deposits of more than 500 fathoms, a line at which some persons draw the distinction between deep-sea and shallow-water faunas. This particular subject, however, is not treated by the author, which disappointed us, as we should have liked to read some account of the newest arguments on this problem.

Another remarkable fact about these animals, but characteristic also of some other groups, is the long persistence of individual species. Mr. Chapman points out that globigerina bulloides "is found in every sea, and certain deep-sea deposits are often chiefly composed of the shells of this type-form." Furthermore, "undoubted examples are recorded from strata of lower cretaceous age, and it is well distributed throughout almost all tertiary deposits up to the present time." This is a most striking fact; as an instance of dogged conservatism it is unparalleled in the animal world. When we add to this that according to the table given by Mr. Chapman (on page 277) there is no family of the order which has become extinct in the long course of time from the Cambrian (when these organisms first appear) up to the moment at which we are writing these lines the wonder becomes intensified. Of these organisms it may be written with literal truth, "Age could not wither ...... their infinite variety." In most groups of animals the past was richer than is the present. The mammal, the reptile, and the fish are all withered and shrunken by the passing of time, but not the foraminifera, which, in spite of their fragile bodies, are, like Rome, built for eternity. In the case of most animals which the naturalist requires for study the proverb, "First catch your hare" is of meaning. The foraminifera, however, lie ready to hand and it is only the "cooking" which presents difficulties, much smoothed by Mr. Chapman's final chapter on Collecting and Preparing. Seeing that according to Plancus (not he who flourished in Horace's younger days ! but more correctly to be called Giovanni Bianchi) an ounce of sand from the Adriatic contains no less than 6000 of these minute creatures, the bag of the collector is not likely to be often empty. At any rate it will not be after reading Mr. Chapman's explanatory pages. It would appear from what the author tells us that these organisms were first noted by the geographer and historian Strabo. His attention was called to the very obvious nummulites of the Egyptian limestones. The first correct notion, however, of the place of these animals in the system is due to Dujardin who demonstrated so recently as in 1835 that they are to be looked upon as protozoa and not as diminutive cephalopoda, a view urged by his predecessors. From that period to the present many illustrious names in zoology appear in connexion with these microscopical animalcules, and Mr. Chapman has put the finishing touch to this gradually growing edifice by presenting us with a plain *résumé* of what is known concerning these small shell-bearing protozoa.

The Treatment of Neurasthenia. By A. PROUST and GILBERT BALLET. Translated by PETER CAMPBELL SMITH, L.R.C.P. & S. Edin. London: Henry Kimpton. 1902. Pp. 213. Price 5*s*.

THIS little book is a really excellent translation of a work by Professor A. Proust and Professor Gilbert Ballet, both of the Faculty of Medicine in Paris and both observers of the very greatest experience in the special department of neurology which is comprised in the title of the book. Neurasthenia is regarded by the authors as a disturbance of the highests and most differentiated functions and a disease which is essentially due to an irritable weakness of the nervous elements. The fundamental symptoms of the affection are persistent headache, insomnia, muscular asthenia, rachialgia, a peculiar mental state, and lastly, dyspepsia due to gastro-intestinal atony. The view that certain visceral derangements, genito-urinary troubles, and anæmia are the primary and fundamental causes of the nervous exhaustion is dismissed as contradictory to the evidence of well-ascertained facts. Indeed, all the functional disturbances observed in neurasthenic patients may be interpreted as etiologically dependent on the primordial alteration of the essential nerve elements, although the exact nature of this pathological alteration is unknown. Among the most important of the exciting causes must be included the cares and troubles of business, reverses in fortune, and the constant wear and tear of living at high pressure. The exhaustion of the lower nerve centres by muscular over-work, sexual excesses, and the toxic influence of alcohol, tobacco, morphia, cocaine, and other poisons, exercise a pernicious influence on the nerve elements, both in the case of the higher and of the lower nerve centres. All the causes above enumerated do not operate with the same frequency or with the same force in different individuals. The offspring of parents who have not been exposed to these exciting causes of neurasthenia will not, as a rule, show any marked susceptibility to similar exciting causes, unless exposed to them to an unusual degree. The accumulated sins or misfortunes of the parents are visited in varying degrees on the children in the form of hereditary predisposition or susceptibility to the diverse stimuli which engender neurasthenia. The more pronounced the hereditary predisposition the weaker the stimuli required to call the disease into being.

The treatment which is recommended in the pages of this little book is essentially common-sense in character and may be summed up in the following words: good moral and physical hygiene, a well-considered dietary, and encouragement by suggestion. Without altogether condemning treatment by medicine the authors believe that, on the whole, more harm than good has been done by drugs to the victims of neurasthenia, and therefore their advice is to rely solely on the principles of natural hygiene—advice with which we are inclined to agree.

LIBRARY TABLE.

The Standard Medical Directory of North America, 1902: including a Directory of Practising Physicians in the United States of America, Canada, Cuba, Mexico, and Central America. Chicago: G. P. Engelhard and Co. Pp 800, large quarto.—We are inclined to agree with the statement of the editors in their preface that the publication of this first edition of their work (which is to be issued annually in the future) has been an "immense task." Although it is obviously difficult for us to express an opinion as to the degree of accuracy attained by the appointment of some 30,000 (!) correspondents to tabulate the lists of those included in the generic term "physicians," it is not difficult to concede that thoroughness has, at any rate, been aimed at, seeing that the total number of physicians tabulated in the directory is given at 122,937, which would work out at one correspondent for under every five names included in the list. (By the way, we may notice that the pagination of the volume jumps from 600 to 701, thus omitting 100 pages.) The contents of the directory include, in addition to its main object, much material information concerning the medical colleges, the medical services, and the medical societies; a digest of medical legislation, including the texts of the Medical Practice Acts of the various States; lists of the State boards of health and of the boards of medical examiners; a very lengthy recital of medical books and periodicals (of which latter there are over 250), and an equally lengthy list of hospitals and sanatoriums. An interesting table at the commencement of the work gives the population of the United States of America at 84,332,610 and the number of physicians at 115,222, equalling 13 666 physicians to each 10,000 of the population; whilst a like comparison for the Dominion of Canada works out at 9 725 physicians per 10,000. Mexico would appear to be the El Dorado of the medical man, so far, at any rate, as the ratio of the profession to the population is concerned—viz, 1·266 to 10,000. The ratio for Great Britain, based on the more or less incomplete 1901 census returns, is 7·2211 to 10,000, and that for Germany is stated to be 5 per 10,000. We not infrequently hear of the overcrowding of the profession in this country, but we appear to be considerably better off than our professional brothers in America. The "Standard Medical Directory" will doubtless prove a very useful work and is a distinct advance on anything we have yet seen claiming to cover similar ground.

The Road to Rome. By H. BELLOC. London: George Allen. 1902. Pp. 448. Price 7*s*. 6*d*.—This is a vagabond book of the best type—of the type, namely, to which belong

Waterton's "Wanderings," "Travels with a Donkey in the Cevennes," "The Golden Ass," and Samuel Butler's "Sanctuaries and Shrines of Northern Italy." We all love wandering, although most of us cannot afford the time wherein to wander. But the next best thing to wandering oneself is to read an account of a journey by a wanderer who can write in the manner of Mr. Belloc. Take the passage about the author's first view of the distant Alps: "Up there in the sky, to which only clouds belong and birds, and the last trembling colours of pure light, they stood fast and hard; not moving as do things of the sky. They were distant as the little clouds of summer, as fine and tenuous; but in their reflection and in their quality as it were of weapons (like spears and shields of an unknown array) they occupied the sky with a sublime invasion: and the things proper to the sky were forgotten by me in their presence as I gazed. To what emotion shall I compare this astonishment? So in first love one finds that *this* can belong to *me*." The Alps are indeed an exceeding great army but yet we think that the solemnity of a solitary mountain like Ararat is even more awe-inspiring. Anyone who has seen those twin peaks rising from the desolate plain will know the sensation to which we refer. The book is full of charming little sketches and we can recommend it as most restful reading to any hard-worked man. Not that we mean by this that on reading it he will feel an "exposition of sleep" but that it will take him out of his worries.

Bird Hunting on the White Nile. By HARRY F. WITHERBY. London: *Knowledge* Office. 1902. Pp. 117. Price 2*s.* 6*d.*—This little book is a record of a trip made through the Sudan for the purpose of collecting birds. The Sudanese birds are by no means well known to English ornithologists and many of them are exceedingly rare. Mr. Witherby, of course, collected with care and discrimination but it is to be hoped that with the opening up of the country the same fate will not overtake the more remarkable birds of the Sudan as has overtaken the bustard and the hoopoe in England. Already the fauna of South Africa is greatly reduced, witness the complete disappearance of the square-mouthed white rhinoceros. Let us hope that measures will be taken to prevent useless slaughter of the avi-fauna of the Sudan.

Savage Island. By BASIL THOMSON. London: John Murray. 1902. Pp. 234. Price 7*s.* 6*d.*—Savage Island, otherwise Niue, lies about 1000 miles N.N.E. of New Zealand. Mr. Thomson went there to proclaim a protectorate at the request of the king of the island. The request was made 13 years previously, but the British Government never does things in a hurry. Mr. Thomson's book is decidedly interesting besides being amusingly written, but it gives the reader occasion to think whether the introduction of Europeans and of European ways has really benefited the natives of Polynesia. True, it has done away with cannibalism and with customs and institutions such as the Areoi but, on the other hand, the introduction of syphilis, measles, and bad whisky is a heavy sum on the debtor side of the account.

A Treatise on Pharmacy for Students and Pharmacists. By CHARLES CASPARI, jun., Ph.G., Professor of Pharmacy in the Maryland College of Pharmacy. Second edition, revised and enlarged. London: Henry Kimpton. 1902. 778 pages, illustrated with 301 woodcuts and a portrait plate. Price 19*s.* net.—As implied by the title, this work is intended chiefly for pharmacists and serves as a text-book for the student and as a handbook for the practising pharmacist. The subjects treated in the book have been grouped under three distinct headings. Part I. comprises General Pharmacy, including the study of weights and measures, specific gravity, the application and control of heat, mechanical subdivision of drugs, and methods of solution and separation, together with a classification and description of the various solvents and products of plants used in pharmacy. This part is mainly of interest to pharmacists and appeals but little to the medical practitioner or student, but those for whom it is especially useful will find no better guide to the details of these pharmaceutical operations.

Part II. treats of Practical Galenical Pharmacy and Dispensing. The subject is divided into chapters dealing severally with the various classes of galenical preparations—e.g., liquors, tinctures, extracts, ointments, and so forth. The modes of making the various modern forms of medication are described—e.g., hypodermic and other tablets, capsules, dermatological pastes, glycero-gelatins, and dermal pencils, but one notable exception may be mentioned, viz., ophthalmic eye discs, which do not appear to be even mentioned. Parts I. and II. are profusely illustrated with excellent woodcuts of apparatus suitable for use both on the small scale and for manufacturing purposes. Part II. is likely to prove of more service to the physician than is Part I. It contains many suggestions of a useful character. Thus, in the case of ointments it is pointed out that glycerin should not be used in place of oil or water to produce a smooth paste with vegetable or mineral powders owing to its tendency to separate from the fats on standing. The presence of a large quantity of glycerin in an ointment is sometimes necessary for therapeutic purposes; in such cases the substitution of a small quantity of anhydrous wool-fat for a portion of the fatty basis removes the difficulty. The occurrence in almost every paragraph of practical notes of this character shows that this part is of great service to the pharmacist.

Part III. is devoted to Pharmaceutical Chemistry and is confined to such compounds as are either officially recognised in the United States Pharmacopœia or are of special medicinal interest. This part is intended to serve as an aid to the study and use of that Pharmacopœia by the inclusion of explanatory notes on the tests and methods of assay. The intention is well realised. The inorganic substances are dealt with first and much acceptable condensation is effected by a judicious grouping of them. Thus, the halogens are considered in one chapter while other chapters are devoted to the compounds of sodium, of potassium, of lithium, and so on. This method of grouping together the various preparations of a given element is more convenient for the prescriber than an alphabetical arrangement, such as is generally met with in pharmacopœias. Here, again, we find abundant evidence of laboratory work and of considerable practical experience. Thus, under "Potassium citrate" we read that the solution should be extemporaneously prepared as it does not keep well and soon loses its refreshing taste. Under the articles on the various well-known organic substances the useful method has been adopted of pointing out their disadvantages, when such are known, and thus of explaining the particular advantages derived from the introduction of the various substitution products. Thus, under "Pyrogallol" it is stated that the poisonous nature of this compound has led to the introduction of the derivative product gallacetophenone. The work is provided with a valuable index and is well printed in bold type. It can be recommended to every pharmacist as a daily companion with confidence and to the physician interested in pharmacy it may be commended as a work of reference.

DIRECTORIES.—*The City of London Directory, 1902* (W. H. and L. Collingridge, Aldersgate-street, E.C., pp. 1222, price not stated), deals exhaustively with the liveries, public officials, and the vast commercial enterprises carried on within the city limits, and is an invaluable book of reference in all matters pertaining to the great centre of business life.—*Sell's Dictionary of the World's Press* (Henry Sell, 167, Fleet-street, E.C., pp. 930, price 7*s.* 6*d.*) and the

Advertiser's A B C (T. B. Browne, 163, Queen Victoria-street, E.C., pp. 1090, price 10*s.* 6*d.*) run on very similar lines and contain much useful information concerning the ever-increasing number of publications issuing from the press in this and other countries.

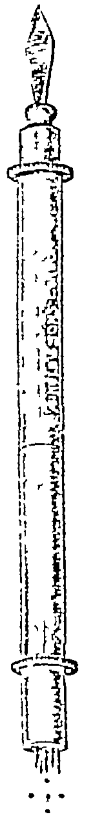
JOURNALS AND MAGAZINES.

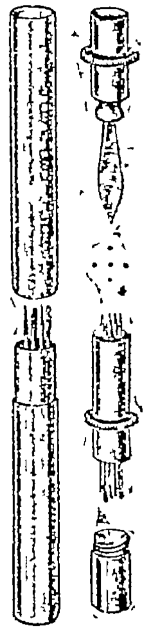
The *Practitioner* for May contains two long and carefully compiled original articles. The first, by Dr. R. W. Philip, deals chiefly with a detailed investigation of the temperature in pulmonary tuberculosis and serves well to show how important in some cases a frequent use of the thermometer may be. Dr. Philip also gives cases showing how the temperature may remain normal in the presence of other signs suggestive of disease in an active state. The second article is by Dr. R. T. Williamson on Acute Anterior Poliomyelitis and teems with references to an almost bewildering extent. Dr. Williamson favours a toxin theory of etiology for the disease. Mr. William Rose describes a successful case of Removal of the Gasserian Ganglion by Doyen's Method. The editorial remarks evince chiefly annoyance at Mr. Rhodes's will.

New Inventions.

A NEW ASEPTIC VACCINATOR.

As the Local Government Board inspectors invariably find fault with the point of the popular Cooper-Rose vaccinating instrument, on account of it not being readily cleansed, and as there is nothing better on the market, I have asked Messrs. Arnold and Sons of West Smithfield, London, E.C., to carry out my idea of one that would remedy that defect, and this they have done most satisfactorily. My vaccinating instrument shown in the illustrations is of the usual pencil shape. One end contains the spatula and the other on being pulled out and reversed reveals a small case perforated with five small holes at the end, through which five ordinary tailors needles can be inserted from the inside of the case, projecting externally two-sixteenths of an inch and kept in their position by a cap which screws on and off, thus allowing the needles to be renewed at any time, while also exposing sufficient of the points to allow effectual sterilising by the flame of a spirit lamp The needles being renewed from time to time do their work most effectually and so gently that children hardly feel the operation, thus avoiding the heavier and painful pressure that is required when immoveable needles become blunted. It is a great advantage to have the needles so easily removeable, for the size of the scarifications can be accurately regulated by using only two or three needles and they should be made as recommended by Dr. C. Renner and not by twirling as when using the Cooper-Rose instrument. Being made wholly of metal all or any part of it can be perfectly sterilised by boiling in an ordinary test-tube. Refill needles are contained inside the instrument which pulls apart in the centre. To arrange new needles in their place the small case is held up to the light and with a pair of forceps they are easily put into the holes; when they are properly placed screw on the cap and fix it on the end of the instrument. This vaccinator has received the approval of the Local Government Board and I invariably find that the use of it removes one of the great objections that mothers have to vaccination, the ordinary lancet usually being a perfect terror to them.

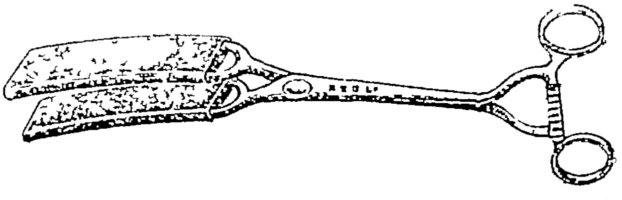




JOHN WILSON, M.D. Edin.,
Public Vaccinator, No. 4 District, Cheltenham.

A NEW CLAMP FOR ABDOMINAL OPERATIONS.

THIS clamp has for its primary object the controlling of hæmorrhage while a wedge-shaped piece of liver is being excised. The idea and the instrument are both novel—the outcome of practical experience—for hitherto the liver has been compressed by the assistant's fingers. Since both hands are necessarily occupied, an instrument which will free the assistant so as to be of use otherwise, and which is so made as to fulfil its purpose without damage to the liver, should be of advantage. The clamp is 11 inches long with a strong rachet catch and a locked joint; it is made of nickel-plated steel. Each blade consists of two slender prongs over which a wide piece of thin rubber tubing is stretched in the manner shown in the illustration; this makes each blade three-quarters of an inch wide and so a broad smooth surface is applied to the liver which will not slip Bearing in mind the thinner anterior border of the liver the blades have been so adjusted as to compress equally the area of liver which is to be removed. The clamp can also be used in gastrectomy, pylorectomy, or enterectomy, when it might be advantageous to have the blades a little narrower. In any case it is argued that hæmorrhage will be efficiently controlled and that no injury to the compressed tissue will ensue. The clamp may be obtained from Messrs Reynolds and Branson, Limited, 13, Briggate, Leeds.



BERTRAM C. STEVENS, M.D., M S Durh.,
Swinton, Rotherham. F.R.C.S. Edin.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next general meeting of this association will be held at 11, Chandos-street, Cavendish-square, London, W., on May 21st, at 4 P.M., under the presidency of Dr. Oscar T. Woods. Dr. Henry Rayner will open a discussion on Sleep in Relation to Narcotics in the Treatment of Mental Diseases. Dr. T. Claye Shaw will read a paper on the Surgical Treatment of Delusional Insanity Based upon its Physiological Study, and Dr. Robert Jones will read Notes on the Treatment of Morphinomania. It is expected that the following gentlemen will take part in the discussion: Dr. Fletcher Beach, Dr. G. F. Blandford, Dr. Harry Campbell, Dr. T. B. Hyslop, Dr. C. A. Mercier, Dr. G. H. Savage, Dr. T. Claye Shaw, Dr. R. Percy Smith, and Dr. T. Outterson Wood. Members will dine together after the meeting at the Café Royal, Regent-street, W., at 7 P.M.

THE LANCET.

LONDON: SATURDAY, MAY 17, 1902.

The Royal Army Medical Corps.

WE published in our issue of May 10th, p. 1339, the text of the new regulations for admission to the Royal Army Medical Corps which were promulgated in the monthly issue of Army Orders for May, 1902. These regulations furnish information upon a number of details which has been rendered necessary by the issue of the Royal Warrant of March last: indeed, they may be regarded as complementary of that document. The qualifications of candidates for commissions, the nature of the appointments, the subjects for entrance examinations and for promotion are all set forth, together with extracts from the recent Royal Warrant with regard to pay and advancement. We cannot spare those of our readers who are nearly interested in the matter the trouble of going through the regulations word by word, for they require to be carefully studied in order to be properly understood. The impression derived from any superficial or cursory reading of them might be that they set forth a scheme which was of too elaborate and complicated a kind, but this was probably unavoidable in the circumstances. Medical students and those of our profession who may be turning their attention to the army as offering a promising and suitable field for their future career like to have the gist of things packed in a small compass and to have the nature and terms of any proposed new undertaking stated in a very plain and simple fashion, so that the appearance of intricacy is to be regretted. We venture to think that the authorities would have better attained the end that they have in view by adhering to some such method of army medical reform as was long ago outlined in THE LANCET. But we may be a little biased in favour of our own scheme, and it must be remembered that new official regulations have to be exhaustive, for they must provide against contingencies that seem remote only until experience brings them close. With a little knowledge of the past history and present condition of the Army Medical Service and a little careful study it *is* easy to unravel the meaning of the regulations and to discover the aim and intention of the authorities in drafting them.

Looking at the new regulations for admission to the Royal Army Medical Corps as a whole, we may assume that the question of the military titles, rank, and status of army medical officers had been already settled in accordance with the wishes of the Army Medical Service and the profession generally, so that there remained for solution the problems as to how medical officers of a high professional standard could be obtained in sufficient numbers for the requirements of the service and as to how the State could have the assurance that that standard would be maintained. The official answer to those questions on the part of the War Office, as we read the matter, is to be found in the new regulations studied in connexion with the Royal Warrant. It will be seen that, according to the new regulations, it is proposed to maintain the efficiency of the whole medical service by increasing the facilities for professional and scientific study and by the institution of a new system of examination with the view of testing the practical qualifications of the individual members of it. These examinations are divided into two classes: one of a purely professional and scientific character; the other having relation more particularly to the duties of military service which military medical officers as such are called upon to perform. Considered in the abstract, there may be little or nothing to be urged against the examination system. But we confess that we have not the same opinion of examinations as a test of fitness and merit that the authorities seem to entertain, and we fear that a multiplicity of tests will have a somewhat deterrent effect on young men who have just qualified for the practice of their profession and who had hoped thereby to have emancipated themselves from further stringent professional examinations. The competitive entrance examination is no longer of a theoretical and academic kind—a mere repetition of the tests that the candidate has already undergone—but it is of a really practical and clinical character and adapted to test the knowledge of a man who is already qualified. This has to be supplemented by the results of a further examination after a course of special instruction in hygiene, in bacteriology, and in the technical duties of the corps—a two months' course of instruction in hygiene seems, by the way, too short, considering the enormous value that a practical knowledge of sanitary science will be to the officers of the Royal Army Medical Corps. The new regulations for promotion to the rank of major are very important, because the medical officer's future will greatly depend upon the result of the examination he will have to undergo at that stage of his service career. If the intentions and provisions of the regulations are properly carried out medical officers will, as it appears to us, have excellent opportunities of preparing themselves for this examination, with the design and object of which we quite approve. We assume that as a matter of course there will be established some sort of medical staff college and that it will be in London where medical officers will be surrounded with opportunities of seeing hospital practice of all kinds and of obtaining any clinical instruction which they may desire.

The new scheme *unquestionably provides for a fairly* liberal increase of pay; the door to professional merit and attainments is now also thrown open in a way which has not hitherto been the case in the army medical service. It goes without saying that these are excellent points. A medical officer of the future will to a large extent be master of his fate. Special opportunities will be afforded him for study and he can accelerate his promotion by success at examinations and can qualify for an appointment with extra pay as an expert in subjects for which he has any special knowledge, taste, and aptitude. There are other points on most of which we have touched in previous articles but to which it may be necessary to recur. Their importance is not as yet as obvious as those which we have selected for notice. We may conclude by saying that, taken as a whole, the Royal Warrant and the new regulations for admission into the Royal Army Medical Corps constitute, in our opinion, a distinct advance on anything which has yet been done to make the Army Medical Service what it should be—viz., a scientific branch of the military service.

◆

The Public Vaccinator's Relations to the Public and to the Profession.

EVEN as war is the opportunity for distinction or failure on the part of the soldier, so, in a certain sense if in a different degree, is small-pox the public vaccinator's opportunity. The country expects each to do his duty and it is only after the storm has passed that the bearing and action of the officer are seen in their proper proportions. With the public vaccinator there is but little scope for what in a martial sense passes for heroism, but the gauntlet which he has to run will win for him either the esteem or distrust of the public body which he serves and the appreciation or the reverse of his medical colleagues. There can, we think, be no doubt that during the stress of the small-pox epidemic the public vaccinators have, as a body, proved themselves not only public servants worthy of the highest trust but also courteous colleagues. This would, we know, be the testimony of the local authorities intrusted with the administration of the Vaccination Acts, as also that of the medical practitioners who have had to perform vaccination in somewhat trying circumstances in consequence of the extensive duties which the present Act imposes upon public vaccinators.

But at times there have unfortunately been indications that in his relations with the local administrative authority the public vaccinator, although he has kept within the letter of the law, has nevertheless pressed home somewhat unduly his claims upon the public purse. Questions such as these do not lend themselves well to discussion, and decisions in regard to them must be arrived at on a basis of good judgment and taste. Many of the narratives which have reached our ears we are unwilling and unable to credit. We are unwilling, for instance, to believe that a public vaccinator would revaccinate his wife at the public expense in his drawing-room when by passing into the surgery the operation could have been performed at a materially smaller expenditure to the ratepayer. But this serves to raise the rather delicate question as to how far a public vaccinator is well advised in vaccinating his wife and family in his official capacity. There is obviously no statutory objection against his so doing, but at the same time we cannot refrain from expressing the opinion that the public vaccinator would be consulting the best interests of the profession to which he belongs by abstaining from entering a fee in his register next to the names of intimate relations living under the same roof with himself. If he prefers the Local Government Board lymph it would be open to him to use it upon such patients, but while entering their names in his register in accordance with his instructions he should omit, as a matter of courtesy to the public, to fill in the columns relative to his fees. Public vaccinators who do not take this view of the situation should bear in mind that any action which is likely to be regarded as somewhat exacting by the guardians and the public is calculated in the long run to exert a prejudicial effect upon public vaccinators as a whole. It is well that the public vaccinator should remember that he is now paid a fee which, if it be not altogether adequate to the work performed, is nevertheless almost as much as he would feel justified in charging in a private capacity. It is this fact which should, we think, prompt the public vaccinator to meet any proposals for revaccination in an adaptable spirit. And above all, the public vaccinator should not, if he can possibly prevent it, afford ground for the suspicion that in cases of revaccination the operation is performed at the residence of the patient rather than at the surgery with the view of securing the higher fee. It may be that already the very substantial sums which are being paid to public vaccinators for revaccinations performed elsewhere than at the surgery will lead in the future to the maximum fee being allowed in connexion *only* with the first case, in houses where multiple revaccinations are performed.

So much with regard to the attitude of the public vaccinator towards the guardians and the public; a word now in reference to his attitude towards his medical colleagues. It would be affectation to assume that the working of the present Vaccination Act has been altogether without unpleasantness in certain directions. If the feeling were traced to its source there would be found faults, or rather perhaps an absence of courteous tact, on both sides. The public vaccinator has doubtless been given enormous powers and facilities and it is for this very reason that he should exercise the greatest forbearance towards his less fortunate colleagues. Unless he does so a decisive reaction possibly awaits him. He may, indeed, find that the distinction which he now enjoys may be taken from him by a stroke of the legislative pen by the simple expedient of creating all medical practitioners public vaccinators with claims upon the public purse. We are fully aware that the public vaccinator has statutory duties that he must perform and the execution of which is sometimes difficult and often very unpleasant. He can, however, effect much in a negative sense; he can refrain from publishing the fact that he alone is entitled to use the Government lymph, or if he must speak highly of the material that he is about to use he should allow in the same breath that his lymph is no better or worse than many other strains on the market. He may, too, refrain from any persuasive action as regards vaccination in the case of children whose names have not yet been placed upon the "H." Form, and of children whom he has not been specifically invited to vaccinate; and finally, he will do well to refrain from persuading those who are in a position to pay for private vaccination that they can be vaccinated equally well by him at the public expense. There is, however, one exception to this negative action, and that is in instances where the public vaccinator, at the request of the medical officer of health, visits a house where small-pox has actually occurred. In this case it is his public duty to urge immediate revaccination upon all the inmates of the house. With the exercise of mutual forbearance there should be practically no friction in the detailed administration of the Act, and seeing that the Act has resulted in an enormous increase of vaccination in the country it is the duty of all concerned to aid in promoting its smooth application.

◆

The Case of Mrs. Cathcart.

After a prolonged inquiry and a very exhaustive medical exposition of her mental condition Mrs. Cathcart has been found by a special jury to be insane and incapable of managing her affairs. Of the correctness of this decision there will be a general endorsement, and it may be taken for granted that whilst her property will in the future be carefully protected and administered she will herself be allowed a measure of comfort and ease in which any element of restraint will be merely nominal.

Some years ago Mrs. Cathcart was the subject of a judicial inquiry as to the state of her mind and her capacity for looking after her affairs but, owing mainly to the powerful advocacy of Sir Charles Russell (as he then was), she obtained from the jury a verdict in her favour. Experience has shown that Mrs. Cathcart was not able to carry out the hopes of her friends in the way that they expected. She has been constantly engaged in litigation of a costly and useless character and finally she was placed in Holloway Prison for contempt of court, where her conduct was carefully watched and noted for several months by the medical officers and the warders. Mrs. Cathcart has for some years suffered from delusional insanity and it seems most probable that she has become worse and that the scope of her delusions and hallucinations has extended to a degree that makes hope of recovery more than doubtful. For her own sake it is to be regretted that she did obtain the verdict in the first trial, as she would otherwise have been saved experiences that must have filled her life with discomfort and worry. At the same time she has had her opportunity and has failed to justify it and the opinions of the medical experts who gave evidence which was not in her favour at the first trial have been amply borne out by the subsequent events. Some criticism has been passed upon the length of time during which Mrs. Cathcart has been detained as a prisoner, but it must be remembered that she had been declared by a jury to be "sane" and therefore she was liable—whatever may have been the general opinion as to the verdict—to all the consequences of responsibility until it was proved that she was not answerable for her actions. A lengthy detention in the presence of her refusal to "purge *her contempt" by means* which were *readily available* was unavoidable, because it appears that the prominent symptoms of alienation were of a recurrent character and that there were times when little could be detected beyond mere eccentricity. Whilst it may seem that her *detention* as a *prisoner*, who was all along suspected of being insane, was unnecessarily long it must be remembered that it is only by a prolonged and carefully recorded examination extending over a considerable time that some of these cases of delusional insanity can be clinically elucidated. If Mrs. Cathcart was not insane she was rightly detained until she had expiated her offence; if, however, *she* was insane it became necessary to establish the proofs in the most complete manner so as not to incur a repetition of what we must call an unfortunate acquittal. There is every evidence that, conformably with the rules, she was treated in the most considerate way in the prison.

The opinion appears to have gained ground that it might be possible for Mrs. Cathcart to manage herself while not managing her estate, and that therefore justice would have been satisfied by placing her estate under the management of a committee whilst allowing personal liberty to herself. We do not agree with this hypothesis. Personality and the objective relations necessarily entailed in the management of property are so fused that it is difficult to see how a person can be mentally unsound as regards the latter and sound as regards the former. In our opinion the *protection of the court* which *is accorded to the estate* is most properly, in this instance, made to include the person. Whatever Mrs. Cathcart has had to endure during the last few months through litigation and enforced incarceration she owes to the powerful effects of advocacy. The medical evidence given on the side of the Crown at the first inquiry has been fully justified by the conduct of the lady during her subsequent career, and any doubts which may have existed in the minds of her sympathisers must now be completely and finally set at rest.

Annotations.

"Ne quid nimis."

THE VOLCANIC DISASTER IN THE WEST INDIES.

A greater and more awful disaster than that which has *befallen* the *town of* St. Pierre in the island of Martinique can scarcely be imagined. It looms larger than did the great historic eruption of Vesuvius and the destruction of Pompeii, of which Dion Cassius wrote (lib. lxvi.), according to the quotation selected by Lord Lytton on the title-page of "The Last Days of Pompeii," as follows: "Such is Vesuvius, and these things take place in it every year. But all eruptions which have happened since *would* be *trifling*, even *if* all summed into one, compared to what occurred at the period we refer to. .... Day was turned into night and light into darkness, an inexpressible quantity of dust and ashes was poured out, deluging land, sea, and air and burying two entire cities, Herculaneum and Pompeii, while the people were sitting in the theatre." Seismic history in this instance has only too fearfully and faithfully repeated itself, and it is *doubtful* whether the volcanic outburst at St. Pierre was less in intensity or involved a lesser area of destruction than that of Vesuvius over 18 centuries ago when it completely blotted out the city of Pompeii. St. Pierre, too, is no more and *the disaster* is complete. It is estimated that no less than 30,000 people were destroyed and it does not seem possible that this immense sacrifice of life could have been prevented. It is reported, however, that the Pelée mountain had exhibited signs of disturbance since April 23rd. But the mere smoking of a volcanic mountain may mean nothing and so no alarm was entertained. So long as the earth contains molten elements within its crust so long must volcanic eruption be possible. It matters little what the exact nature of these immense explosions is—a consideration of the great potentialities of the earth, *sea, and air* will *readily yield* an infinity of explanations as to their occurrence. The intense violence of a volcanic outburst probably has its origin in the sudden evolution of steam by water from the sea or rivers gaining access to intensely hot subterranean fires. With slight explosion the result may be an earthquake with perhaps no evidence of volcanic eruption at all. All depends upon the resistance which the earth's crust is able to offer. There are lines of weaknesses in various parts of the earth and these lines correspond with volcanic districts and regions where earthquakes and earth tremors are in evidence. The true earthquake makes itself felt all over the world, whereas the volcanic disturbance does not, because the force in the latter instance has found vent. Professor Milne in the Isle of Wight is thus able by means of his delicate seismological instruments to detect earth tremors occurring at any part of the earth. The terrible disaster at St. Pierre and St. Vincent has cast a painful gloom over the whole civilised world and intense sympathy has been universally expressed. It is, however, some consolation to reflect that the wholesale destruction of human life by rivers of molten lava deluging a town or by the incessant hail of hot sulphurous cinders filling the air does not necessarily imply an agonising death. On the contrary, it is probable that, in some instances at any rate, there is no struggle—the vapours of lava would quickly overpower and render the victims senseless and in this state they would probably be overcome by asphyxiation and die. There would appear, again, to be some evidence that phenomena similar to those of lightning accompany volcanic explosions. Such is reported to be the case at Martinique and Lord Lytton, in a note in "The Last Days of Pompeii," says: "The volcanic lightnings introduced in my description were evidently among the engines of ruin at Pompeii." It is not definitely established, we believe, that an electrical disturbance is necessarily associated with volcanic eruptions, but from some accounts of the Martinique disaster it would appear that many bodies presented the appearance of having been struck by lightning. The mystic forces of the earth's interior can indeed work immense destruction to life and property and yet strange is it to reflect that human life would cease to be possible on the earth's surface were these subterranean fires to be extinguished. Volcanic disturbances are an indication of the earth's vitality and when these cease the earth will be as uninhabitable and just such a cinder as is the moon. The complete sympathy of the whole human race has declared itself and it is devoutly to be hoped that this sympathy will assume a very practical shape, that speedy relief may be secured, and that that worst of all sequelæ, famine, may be averted. Human help can do no more in such a terrible disaster.

MEDICINE AND THE TEACHING OF THE GOSPEL.

THAT the medical branch of the Church Missionary Society has proved a powerful auxiliary to the parent society in its endeavour to spread the teachings of the Gospel is shown by the satisfactory report of the Medical Mission Auxiliary which was presented at a meeting presided over by the Bishop of Kensington at St. James's Hall on May 8th. During the year 1901 the number of medical men on the roll of the society has been increased to 68 and there are now a total of 1688 beds in the society's hospitals, as compared with 1613 in the previous year. The number of in-patients has increased from 11,890 to 14,470, and in the out-patient department more than 100,000 additional attendances were registered. However, it is not at all satisfactory to know that the medical work of the auxiliary is being seriously crippled in several important centres for want of suitable buildings, especially in Gaza, Ispahan, Kirman, Fuh-chow, and Kien-King. The Financial Committee earnestly appeals for gifts towards building new hospitals in these places. The total expenditure of the year under notice was £20,773, as against £17,962 in the previous year, and the balance-sheet shows a deficit of £5920. There can be no doubt that the secret of the success of the medical mission lies in the fact that medical men hold the key which can unlock the doors to hearts which would otherwise remain closed—the key of sympathy, as the Bishop of Kensington happily termed it. The great beauty of the medical mission, he added, was that the outcome of the highest human science and skill was consecrated to the service of Christ. Accounts of the work done at the various stations which the speakers represented were given respectively by Dr. E. F. Neve (Kashmir), Dr. A. R. Cook (Uganda), Dr. B. van Someren Taylor (Hing-Hwa), and Mr. H. White (Yezd).

MOSQUITOES AND MALARIA.

WE have received a copy of a lecture delivered at the Dalhousie Institute, Calcutta, on April 8th of this year by Dr. T. Frederick Pearse on Mosquitoes and Malaria. Many such lectures and addresses have, of course, been delivered during the past two years, but there is always room for a
good, clear, popular exposition of the complicated path
logical story implied by the title. And Dr. Pearse's p
was a good *résumé* of the results of the investigations
have been made as to the causal relationship of the m
to malaria, couched in the proper phraseology for a di
not intended for an entirely medical audien

We further draw attention to a contribution by Dr.
Manson which we publish in another column, en
"The Diagnosis of Malaria from the Standpoint
Practitioner in England." He points out that malaria
too frequently assumed to be present in patients in
country when no such taint exists. He arranges
pathognomonic indications of malarial infection under th
headings: (1) the clinical; (2) the therapeutic; and (3) the
microscopical. Dr. Manson's remarks will well repay perusal. Practitioners in this country have but comparatively few opportunities of observing cases of malaria and hence are liable to fall into error. The clinical manifestations are discussed in an original and most instructive manner. Dr. Manson maintains that there is only one clinical symptom that justifies a positive diagnosis—this is periodicity. He further states that his experience has made him formulate a rule which he recommends to practitioners: "Have absolute confidence in tertian and quartan periodicity as a basis for a diagnosis of malarial infection, but distrust, or rather absolutely disregard, quotidian periodicity." therapeutic test, is probably generally well known; the microscopical, as Dr. Manson admits, is of value only in the hands of the expert microscopist.

REPRINTS—SUGGESTIONS TO MEDICAL WRITERS.

DR. J. MADISON TAYLOR of Philadelphia, U.S.A., has contributed to the March number of the quarterly journal, *Medical Libraries*, published at Denver, Colorado, U.S.A., some hints for facilitating reference to medical papers and records. His suggestions in brief are:—

1. The size of sheet should be more uniform. 2. Authors should send duplicate copies of every paper to certain libraries, so that they may be filled under the heading of "Author" and under the heading of "Subject." 3. Reprints should be filed at the hospital from which clinical material has been obtained 4. The notes of hospitals, so far as they are common property, by staff or writers should be marked in some clear way with the name or initials of the author, or reference should be made to the article.

r. Taylor's ideas, so far as they apply in this country, are orthy of consideration, but his suggestions are fulfilled by own columns and those of the *British Medical Journal* way that he hardly realises, living in a country some- ppressed by the multiplicity of medical publications. mon for us to publish a paper containing a *résumé* s of a certain disease observed in a certain hospital ain dates. Future observers by consulting our where they should take up the tale. In the s of America such summaries may be hidden in 50 journals and to search for them is an arduous hich hardly repays the necessary trouble.

ONDITIONS RESULTING IN HOMICIDE.

ty of investigating homicidal conditions and homicidal tendencies in insane patients is *Journal of Mental Science* for April last Dr n, resident physician for the Asylum for tics at Dundrum, Ireland, discusses this t. The paper is based upon the study of 49 were admitted to the asylum after trial for hter and of one patient who was charged icide. Females were excluded from the ation as their cases were of a totally different vington points out that wives were the com- s, then children, and then parents and sisters attempted homicide was of special interest as the development of homicidal passion and was worked out owing to the escape of the intended o furnished many particulars. The patient was ed 38 years, married, the father of two children. as syphilitic and of intemperate habits, and feeling lf growing prematurely old while his wife remained ghtly and attractive he became suspicious of her and hed for indications of infidelity, as he imagined she was "tired of him and wanted a change." developed hallucinations of smell and taste, searched s room to ascertain their cause, and thought that vapours rose from the floor and that the flower-pots were watered with noxious chemicals These delusions alarmed his wife who consulted a medical man, with the result that the patient, now growing more suspicious than ever, thought that he tasted medicine in his food and imagined that he was being poisoned. He accused his wife of being a wanton and the frightened woman, anxious to protect herself and her children, foolishly invited a male friend to sleep in the house. He was now more than ever firmly convinced of his delusions and one night he crept into his wife's room with a hatchet and struck her a violent blow. She was badly wounded but recovered at length after her life had been despaired of. This case, says Dr. Revington, illustrated the fact that "homicide was a potentiality in almost all cases of delusion and hallucination, and that whether homicide occurred or did not occur was a matter of environment and of the length of time that elapsed before safety was sought within the walls of the asylum" Investigation of the remaining 49 patients led to the conclusion that homicidal lunatics were as a rule insane before they attempted murder, generally for some years. Five of these patients suffered from congenital mental defect and one each from epilepsy and general paralysis; in 20 of the other cases acute frenzy or visual hallucinations or "voices" prompted the patient to murder. Many of the others were alcoholic subjects, but there remained 12 cases where the cause could not be traced owing to absence of information or the demented condition of the patient. There existed, says Dr. Revington, no special homicidal mania, the ordinary motives of jealousy, misery, rage, or acute fear, combined with some mental weakness or disorder, furnishing the chief causes of homicide.

THE LIME-WASHING OF FACTORIES AND WORKSHOPS.

AN order has been issued by the Secretary of State granting special exceptions in regard to the lime-washing of factories in the case of electric generating works and lace-factories. A special exception will only be granted when in the factory a space of 2500 cubic feet space is afforded for each person employed therein. Of course, the order has not removed the obligation of keeping the factory in a cleanly state as prescribed by a subsection of the Factory and Workshop Act, 1901. Indeed, if it be shown that any part of a factory to which this exception applies is not in a cleanly state the occupier will be required to limewash the premises in accordance with the main requirement of the Act. The Act provides that the walls of factories if they have not been painted with oil or varnished once at least within seven years shall be limewashed once at least within every 14 months. The Secretary of State is apparently of the opinion that in electric generating works and in the frame dressing-rooms of lace-factories in which the number of cubic feet of space bears to the number of persons employed therein at one time a proportion of not less than 2500 to every person, cleansing by limewash is not imperative.

HONOURS TO PROFESSOR VON LEYDEN.

OUR correspondent in Berlin writes: The seventieth birthday of Professor von Leyden, the celebrated physician and clinical teacher, was celebrated here in an impressive manner The large hall of the Philharmonic Building in Berlin was the scene of the proceedings, which were organised and effectively carried out by a committee consisting of former and present assistants, as well as other professional and non-professional friends, all acting under the general direction of the president, Professor Nothnagel of Vienna. When Professor von Leyden entered the hall, which was well filled, he was welcomed by the strains of a band of music, escorted by the committee to his place on the platform, and formally congratulated by Professor Nothnagel in a remarkably appropriate address introducing an outline of his personal history and specifying some of the more important features of his work. A great many deputations were then received, all of whom either delivered addresses or brought gifts, including contributions in aid of the benevolent institutions under Professor von Leyden's patronage. The first deputation was that of the Army Medical Corps, headed by General Staff Surgeon Dr. von Leuthold, it was followed by a long succession of delegates representing foreign and German universities, medical societies, and other professional and scientific associations; the former and present assistants attended to pay their respects in person. Finally, a deputation representing the medical press was introduced, bringing copies of their respective journals issued for the occasion with dedications to Professor von Leyden. The proceedings lasted about three hours, during which the venerable object of so much enthusiasm is said to have spoken 28 times in reply to the various addresses and deputations. In the evening there was a banquet at which about 500 guests were present. The Verein für Innere Medicin, of which Professor von Leyden was the founder, held a separate celebration on its own account in Berlin a few days afterwards, with a special meeting of the society and a dinner as the principal events.

THE DISTRIBUTION OF PLAGUE.

THE distribution of plague throughout Egypt during the week ending May 4th was as follows: 3 cases and 1 death at Alexandria, 1 case and 2 deaths at Mit-Samanoud, 2 cases and 2 deaths at Deshneh, 2 cases at Tala, 1 case and 1 death at Beni-Mazar, 2 cases and 1 death at Benha, 2 cases and 2 deaths at Tookh, 1 case and 1 death at Tantah, and 8 cases and 5 deaths at Maghagha, making a total of 22 cases and 15 deaths. Cases have been reported from Syaffa in the Toukh Markaz and from Ezbet near Benha. In the neighbourhood of both these places cases had occurred previously. A telegram from the officer administering the Government of Hong-Kong which has been received at the Colonial Office states that 24 cases of bubonic plague and 19 deaths are reported for the week ending May 10th. In Cape Colony for the week ending April 19th 33 cases of plague were reported, five being Europeans and 28 belonging to the coloured and native population. There are 40 cases of plague in hospital at Sydney.

THE SIMULATION OF ABDOMINAL BY THORACIC INFLAMMATION.

AT the Clinical Society of London Mr. H. L. Barnard has recently called attention to the simulation of acute peritonitis by pleuro-pneumonic diseases,[1] a fact which seems to have escaped the notice of writers. He described cases of pleuro-pneumonia, pyo-pneumothorax, and pleurisy in which the abdomen was acutely tender, painful, and rigid, respiration was costal, and there were frequently nausea, hiccough, and vomiting. In some cases the onset was sudden with collapse like that of perforative peritonitis. The *Boston Medical and Surgical Journal* of April 17th contains an interesting paper by Dr. Maurice H. Richardson on a very similar subject—the simulation of appendicitis by acute intra-thoracic disease. He relates a series of cases in which acute abdominal pain with or without other symptoms suggested appendicitis so strongly that a surgeon was summoned. In one case even excision of the appendix was performed. A boy, aged six years, complained of pain in the right side and headache, vomited, and could retain nothing in his stomach. On the fourth day a medical man saw him and found that there was pain in the right iliac region at McBurney's point. The abdomen was tense and the temperature was 104·5° F. On the fifth day Dr. Richardson saw the patient. The pulse was 120 and the respiration was 40. The abdomen was distended and tender everywhere, the legs were drawn up, the respiration was noisy and rattling, the cheeks were flushed, and the eyes were sunken. Acute appendicitis was diagnosed and the boy was sent to hospital. The surgeon on duty accepted the diagnosis without question and removed an appendix which was thought to be the seat of "catarrhal inflammation." Later a right empyema was discovered. Recovery followed resection of a rib and drainage. Dr. Richardson points out that the temperature of 104·5° (which is unusual in appendicitis), the
wheezing, and the respiration of 40 should have aroused
suspicion of thoracic disease. But the abdominal symptom
misled him. He relates four other cases—three in youn
children and one in a man, aged 35 years—in which th
experience of the first case put him on his guard and enable
him to avoid error. Thus, a boy, aged four years, wa
taken ill with cough and restlessness. On the third da
the temperature was 103° and the respiration was rapid bu
there were no signs of pulmonary disease. Next day th
temperature was normal and he felt well, but in the evenin
the temperature rose to 101·5°. On the eighth day he com
plained of abdominal pain when he coughed. Repeate
examinations failed to explain the cause of the rapid respira
tion. The slightest touch over McBurney's point caused th
boy to complain vehemently. As the practitioner in attend
ance suspected appendicitis Dr. Richardson was sent f
on the following day. The pain seemed severe and th
boy complained of it when he moved. There had bee
vomiting. The abdomen was distended and tender a
over but especially in the right iliac fossa. There wer
abundant pulmonary râles. It seemed wise to wait. On th
following day signs of pneumonia began to appear. Th
abdominal symptoms disappeared in two days and recove
followed. In cases of thoracic disease with abdomin
symptoms the diagnosis usually is not difficult if suspicion
aroused as to the real nature of the case. But when sympton
of thoracic disease are not obtrusive and when those
abdominal disease are the unwary practitioner may easi
be dominated by the idea of abdominal disease and, not car
fully examining the thorax, may fall into error as in the fir
case related. Mr. Barnard regards as of chief importance i
pointing to the correct diagnosis the rapid respiration (
and upwards), the slow good pulse (under 100), and th
softening of the abdominal wall on inspiration. Th
pathology of such cases, as he points out, can be explaine
by "referred pain." Irritation in continuity of the low
six dorsal nerves would cause abdominal hyperæsthesia an
spasm.

SUNSHINE AND COLD.

IT is in the experience of everyone that cold in May
very uncomfortable and trying, a feeling that is possib
accentuated by the ever present suggestion of what Ma
could be according to the best tradition about th
"merrie" month. There is no evidence, however, that th
cold of spring has the same unfavourable effect in gener
upon the public health as has the cold of autumn and winte
According to the weekly vital statistics the present spell
cold weather does not seem unfavourably to have affecte
the death-rate—not even the mortality arising fro
diseases of the respiratory organs. On the contrary, th
mortality has been steadily diminishing during the past fe
weeks. Undoubtedly the sun in springtime compensates f
a good deal, although the warmth of its rays may not
felt. There is no warmth in the chemically active rays
the sun, those rays which stimulate plant and animal li
and yet which are so highly destructive to the materies morb
And it is a significant observation that in April and Ma
despite the cold winds that may prevail, the actinic pow
of the sun's rays reaches a maximum. At no other tim
of the year, not even in the hot days of July and Augus
are the health-giving rays of the sun so intense. Th
fact may probably account for the greater unfavourab
influence on health of cold in autumn and winter wh
the actinic rays of the sun are at the minimum degr
of intensity. Genial warmth is, of course, an importa
factor in the maintenance of the health standard, but the
can be little doubt that the sunlight of spring possess
a greater compensating power over influences for evil tha
does that of the winter. Besides, the days of spring a

---

[1] THE LANCET, April 19th, 1902, p. 1110.

were those of typical cerebral infantile paraplegia. The left lower limb presented a very different appearance. The entire limb showed atrophied and completely flaccid muscles. The condition was that of infantile spinal paralysis. This case bears out the view advocated both by Strümpell and M. Marie that infantile cerebral paraplegia is due to a lesion of the motor area of the brain—polio-encephalitis—analogous to the spinal lesion—anterior poliomyelitis—of infantile paralysis. This analogy is borne out by some other cases. Möbius has described the case of a girl, aged 18 months, who was attacked with infantile spinal paralysis at a time when her brother was suffering from cerebral infantile hemiplegia In 1894 M. Ramy published in the *Revue Neurologique* the case of a man, aged 43 years, who had infantile spinal paralysis of the right leg At the necropsy there were found patches of meningo-encephalitis affecting various convolutions and a focal spinal lesion in the lumbar region, with atrophy of the anterior roots of the lumbar and sacral nerves on the same side. In the same year Neurath of Vienna in a necropsy on an infant, aged five months, found lesions of the internal capsule and centrum ovale with the lesions of infantile spinal paralysis. Beyer, in 1895, published the case of a woman, aged 22 years, who had had since the age of five years left spasmodic hemiplegia and who had suffered since the age of 12 years from attacks of epilepsy At the necropsy, in addition to porencephaly of the right hemisphere there was a focus of anterior poliomyelitis. M. Marie pointed out that his case was a new example of the coincidence of infantile spinal paralysis and the cerebral lesions which in the child produce almost indifferently hemiplegia, diplegia, and paraplegia, and that from the point of view of general pathology the case showed the analogy, it might almost be said the identity, between the cerebral and spinal lesion.

BALDNESS AND DISEASE IN THE BARBER'S CHAIR

FROM time to time we have called attention to the risk of contamination arising from the promiscuous use of brushes, scissors, razors and other implements, at hairdressers' establishments. Recently the New York Board of Health have confirmed such warnings by issuing an official statement, pointing out that a number of diseases can be communicated by barbers. The suggestion is even thrown out—and this is more likely to alarm the general public—that barbers are perhaps the cause of premature baldness. When this occurs a germ is supposed to attack the roots of the hair and this microbe may be conveyed from one head to the other by a brush. Many young men are bald who cannot be accused of riotous living, and it is often difficult to account for such cases of alopecia Perhaps it was the hair dresser's fault. In any case the New York Board of Health urges that greater precautions should be taken—that barbers should constantly wash their hands, in antiseptic solutions, should sterilise their razors and scissors, should protect their utensils from dust, and throw away their alum sticks. If rubbed on a cut or pimple the alum stick may convey blood, pus, and pathogenic bacteria to the next person to whom it is applied Thus loathsome diseases may be contracted from the surface of the alum ointment stick used in America. The question therefore arises whether the barbers will endeavour to meet these new exigencies Historically speaking, the barbers, whose precursors used to be barber-surgeons, should readily appreciate the advantage of antiseptic surgery and be willing to apply its principles to the minor and painless operations which they now perform. Trivial as these operations may seem they are not absolutely free from danger, and to our knowledge some barbers both in Paris and in London,[1] have already introduced antiseptic principles into their hair-dressing saloons. They sterilise their metallic combs, their scissors, and their razors by passing them through a flame each time that they are used, and it would be well if these and other precautions were more generally applied.

THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of The Mauritius, received at the Colonial Office on March 29th, states that for the week ending March 28th there were 5 cases of plague of which 4 proved fatal As regards the Punjab, assuming that there is no mistake in the figures, the news from India, as will be seen from our Indian correspondent's letter at p 993 regarding the presence of plague in the Punjab, is somewhat appalling According to the telegraphic intelligence through Reuter's Agency the number of deaths from plague in the Punjab is now averaging nearly 70,000 monthly Special measures, it is stated, have been taken to prevent the epidemic from reaching Simla As regards Egypt, during the week ending March 23rd 7 cases of plague and 2 deaths from the disease have been reported throughout all Egypt. 1 case occurred at Kom el Nour, 3 cases and 1 death at Dechnoh, and 3 cases and 1 death in 2 nomadic camps near Benha All these cases occurred among the native population.

THE HISTORY OF ATROPINE

VERY nearly a century ago it was just being realised that certain plants contained definite bases yielding definite salts when treated with acids These bases are, of course, well recognised now as the alkaloids, containing amongst their number some of the most powerfully poisonous bodies known to us. In about the twentieth year of the last century these new weapons of the poisoner were on the eve of being discovered as chemically definite principles According to THE LANCET of March 28th, 1824, as will appear from a glance at the 'Looking Back column in our issue last week, atropine had evidently been isolated in that year although probably not in a state of purity Still, a definite chemical principle was recognised, for in this column we read as follows "The property of dilating the pupil, peculiar to these plants [belladonna, datura, &c.], depends on a chemical principle, each of them containing an organic alcaline substance, which can neutralise acids, and form with them salts capable of crystallisation and possessing very powerful properties. This chemical principle has been named *koromegine*, from its power of dilating the pupil.' The existence of the active principle or alkaloid of *Atropa belladonna* was first announced in 1819 by Brandes, although apparently it was not obtained in its pure state until 1833 by Mein, a German pharmacist In the excerpt from THE LANCET of Sunday, March 28th 1824, which was printed in our columns last week it is stated that at the Royal Institute of France Dr Runges, Professor at the University of Berlin, described, amongst other things, a new method of detecting the narcotic principle of the *Atropa belladonna*, *Hyoscyamus niger*, and *Datura stramonium* in cases of poisoning by those plants. The method was simple and crude and consisted merely in boiling the stomach or intestines of the animal poisoned by these vegetable substances and evaporating the aqueous solution to the consistence of an extract and applying it with a camel hair pencil to the eye of an animal. Nowadays, of course, better and more delicate means are employed for isolating the alkaloid from complex organic mixtures. The method, shortly, is to exhaust the mixture with acidulated alcohol. After straining through muslin the longer. That the energy of the light of the sun is greater in spring is abundantly proved by the degree of its photographic effects—effects which are analogous probably to its action upon the human organism, thus favourably influencing the powers of nutrition and raising the degree of resistance of the body to disease. Certain chemical compounds prove to be more readily decomposed and at a quicker rate in April and May than in any other months of the year. Chloroform, potassium iodide, hydrogen peroxide, and a great number of chemical salts give greater evidences of the disturbing action of light in the spring than in any other season, and nature herself responds to this quickening power, for growth is greatest and most vigorous when the chemical activity of the sun's rays is highest, and that, of course, is in spring. There need therefore be no cause for despair that the health will necessarily suffer because of a cold spring, for, fortunately, the rays of the sun are richest in vital agencies at this period of the year and undoubtedly these prevent and mitigate much mischief that would otherwise ensue.

CLINICAL STUDY FOR QUALIFIED MEDICAL MEN.

THE Association of Metropolitan Schools of Medicine is enlarging its boundaries. All the institutions which are recognised by the University of London as places of medical education have been invited to join in the work and we are informed that with very few exceptions they have consented—the addition being announced of such important institutions as the Royal London Ophthalmic Hospital; the Brompton Hospital for Diseases of the Chest; the Hospital for Children, Great Ormond-street; and the National Hospital for the Paralysed and Epileptic, Queen square. The special departments of the general hospitals are also to be organised for the delivery of clinical lectures and demonstrations. London should be a great centre of post graduate work and instruction and the Association of Metropolitan Schools of Medicine has a great future before it in the organisation of a scheme of clinical study for qualified medical men, forming a complement to the undergraduate teaching of the University of London. The office of the association is at the Examination Hall, Victoria Embankment, W.C., where all information concerning the working of the new departure may be obtained.

INSURANCE AGAINST SMALL-POX.

THE *Local Government Chronicle* has recently published some interesting particulars which it has obtained in reference to the extent to which persons have tried to safeguard themselves by insurance at "Lloyd's" against the effect of an attack of small-pox. The following is an extract from the particulars referred to:—

> Insurances are effected from £100 to £10,000 on individual lives but in every case revaccination within a year is insisted on. The nominal rate for a person living in a place where small-pox has not occurred is 2s 6d to insure the payment of £100 if within 12 months the person contracts small-pox, but these rates are increased according to localities. The following are the rates now prevailing in certain districts in London, but they apply to persons in business or professions of good class and not connected with docks or with institutions where small-pox is likely to prevail. The rates are: in Wandsworth, Hammersmith, Ilford, Seven Kings, Battersea, and Camberwell, 3s 4d. per £100; in Tottenham, Dalston, Hackney, Islington, Bermondsey, Lambeth, Leyton, Wanstead, Walthamstow, Gravesend, Romford, Barnet, Glasgow, Southend, and Liverpool, 5s per £100; in Edmonton, East and West Ham, Forest Gate, Rotherhithe, Mile End, Deptford, Plaistow, Poplar, Bow, Woolwich, Greenwich, Stratford, and Charlton, 10s per £100. In certain districts where the conditions are recognised as unfavourable these rates do not apply and special terms have to be arranged in the case of each applicant. Amongst the places so classified are Stepney, Shoreditch, Dartford, Crayford, Bury St. Edmunds, Orsett, and Grays.

We note that certain occupations are specially dealt with—viz., medical men, publicans, undertakers, and butchers—and that there are special rates for families and schools. Many thousands of policies are said to have been issued, the money being, of course, payable in the event of an attack, whether fatal or not. Lloyd's would seem, therefore, to have made a good thing out of the epidemic, for when all is said—and we have no wish to minimise the importance of the epidemic which has not yet really abated—the number of cases has not been very large. The *Local Government Chronicle* calls attention to the element of risk that will be present at the time of the Coronation, when the class of people amongst whom the disease has made its greatest ravages will be gathered together. The warning should stimulate persons coming to London for the ceremony to be vaccinated and revaccinated.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

A GREAT effort will be made, we understand, to raise the Metropolitan Hospital Sunday Fund this year to £100,000. A friend to the Fund has most generously promised to add one-fourth to the amount raised this year in the churches and chapels. Last year £40,000 were raised by these collections; if £80,000 can be raised this year the coveted total of £100,000 will be secured through one donor's splendid munificence. Hospital Sunday is June 15th. We beg our readers to bear the date in mind. It is not too early for them to begin to use their influence in behalf of the Fund, which has for its patron the King and should in Coronation year achieve a record.

UNUSUAL FORMS OF NERVOUS PROSTRATION FOLLOWING OPERATIONS.

THOUGH not of frequent occurrence it is nevertheless important to recognise the fact that in some patients severe nervous prostration and even serious mental disturbance may follow directly upon surgical operations—a group of affections to which the term "post-operative psychoses" has been applied and reference to which was made in these columns three years ago.[1] Dr Charles W Burr, professor of mental diseases in the University of Philadelphia, points out in a contribution to the *Philadelphia Medical Journal* of April 19th that physicians are occasionally called upon to treat severe neurasthenia supervening in women and less commonly in men upon surgical operations. These were cases where, although the visible cause of disease had been entirely removed by surgical means, the patient did not regain health but suffered from marked weakness, lack of mental power, deficient emotional control, and general neurasthenia. Dr Burr cites, for example, the case of a young man, of previous good health but of a type common in America, "over refined, over-cultivated, with nerves not wholesomely blunted but altogether too fine-edged," who was suddenly seized with appendicitis. He was accordingly operated on at once; the wound healed quickly, there was no fever, and surgically the case was quite successful. Yet he continued weak and prostrate after the operation and he remained in bed for several weeks with sheer physical weakness and nervous prostration and it was only after some months of treatment that he fully recovered. The same untoward results, says Dr Burr, followed the crushing of an arm in another patient—a [illegible] muscular man who was a highly emotional subject though he had great self-control. Dr. Burr also points out that women of nervous temperament, unable from childhood to withstand well the wear and tear of life and suffering from chronic pelvic or other disorder not progressive and not dangerous to life, are specially liable to such forms of nervous trouble and prostration after operation. Such a case, it is urged, should not be treated surgically at once when the diagnosis is made. It will be found that the patient is tired and worn out, anæmic, suffering from loss of appetite and from constipation, and that she has vague pains about the body and queer, indescribable sensations about the head accompanied by insomnia. The only organic disease to account for these symptoms is apparently some trouble in the genitalia. Such a patient should not, says Dr. Burr, be operated on until the general health and nutrition have been built up by regulated diet, rest in bed, tonics, massage, and proper mental occupation. This will take some weeks but she will regain weight and colour and become cheerful, and the shock and prostration after the operation will be less and recovery will be quicker in coming. Sometimes, adds Dr. Burr, operation will be obviated entirely.

---

[1] THE LANCET, June 3rd, 1899, p. 1508, annotation on Paralyses and Psychoses following Prolonged Anaesthesia.

THE DESTRUCTOR NUISANCE AT TORQUAY.

In the issues of THE LANCET of Jan. 25th, Feb. 1st, and Feb. 8th, at pp. 262, 335, and 404 respectively, we gave an account from the pen of our Special Sanitary Commissioner of the destructor nuisance at Torquay and of the various steps which the Town Council had taken with a view to abate the nuisance. We also made some suggestions as to what might be done in the situation. We see that at the monthly meeting of the Town Council held on May 6th a report by the sub-committee of the Destructor Committee was brought up for consideration. This report contained a statement by Mr. George E. Davis of Manchester, the expert who had been employed by the Town Council to advise it. Mr. Davis commenced his inquiry in November, 1901, and as a result of his researches various alterations were made in the destructor, which began working again on Dec. 23rd, 1901. Mr. Davis made a final investigation on March 18th, 1902, and reported that matters were satisfactory. There was no organic odour left in the chimney gases and the odours of unburned paraffins, of which he had complained in his first report, had entirely disappeared. The white vapour issuing from the chimney, according to him, consisted of sulphate of potash in an extremely fine state of division. It was quite harmless. Finally, continued Mr. Davis—

> I may add that the destructor will now give you a perfect combustion, even under very adverse conditions, and if you issue an instruction, which is carried out, that no refuse of any kind be charged into the destructor after any interval of stoppage until the temperature of the main flue at the point of entry to the combustion chamber has by preliminary heating reached 700° F., I am of opinion that you will not receive any more justifiable complaints.

Fortified by this report, Mr. Alderman Cumming contended that there was now less noxious matter issuing from the chimney of the destructor than from the chimney of any cottage in the Upton Valley. So much for the Town Council, which seems quite satisfied with the present condition of things. Dr. Henry Humphreys, however, writes to us under date May 8th to say that the smells are by no means done away with. He allows that less dust is blown up the chimney but he says that when the wind is in the north he and his household suffer greatly from the noisome vapours. This was notably the case on May 5th and 6th, when the wind blew from the north. Probably, therefore, the remedies suggested by Mr. Davis, excellent as far as they go, do not meet the prime cause of the trouble, with which the position of the chimney-top has much to do. At all events, the statements made in the report, together with those made by Mr. Alderman Cumming, are directly at variance with those made to us by Dr. Humphreys, and Mr. Davis's opinion that the Town Council will receive no more justifiable complaints looks as though it required modification. If every cottage chimney in the Upton Valley district gives as many unpleasant manifestations of its presence as, according to Dr. Humphreys, the destructor does in certain circumstances, we think that the Town Council must expect to hear more of the matter. But, further, the output of coal smoke upon which Mr. Alderman Cumming lays stress is likely to be augmented by the transference of the electric-lighting station into the unfortunate Upton Valley. And hereby hangs a tale. The issue of the *Torquay Directory* containing a notice of the meeting of the Town Council to which we have just referred contains also a report of the adjourned proceedings at which the Torquay corporation appeared at the Torquay Police-court on May 5th in answer to a summons issued at the instance of Commander Milne on behalf of the Royal Torquay Yacht Club. The corporation was charged with committing a smoke nuisance at the electric-lighting station. The corporation through its legal adviser pleaded that although nothing in the nature of a legal offence had been committed yet the complainants had probably suffered inconvenience. The corporation was doing everything possible to prevent nuisance and annoyance and would continue to do so. The bench allowed the summons to be withdrawn and the corporation paid the costs. There never was a smoke prosecution yet in which the defaulters did not say that they were doing, or had done, or would do, everything to prevent a nuisance. Also it is generally pleaded that the nuisance is either the fault of old boilers and furnaces, or new boilers and furnaces, or of lack of Welsh coal. The nuisance and the filthy smoke are never any person's fault. We hear that, under the reminder of the police-court, the corporation, which had previously contented itself with the usual *non possumus*, has now become active and that the volumes of thick smoke which lately disfigured the harbour are now not visible. We hope that Commander Milne will keep an eye upon the electric-lighting works and apply for more summonses if necessary.

THE LATE R. B. ANDERSON FUND.

SIR C. C. KNOLLYS, K.C.M.G., Colonial Secretary of Trinidad, in a letter bearing date April 19th, reports the receipt by him of the sum of £258 15*s.* 6*d.* subscribed to this fund, and the expenditure of that amount in the purchase and repair of three removeable wooden houses in Port-of-Spain by his instructions on behalf of Mrs. Anderson and her twin sons. In one of these houses she will reside, while from the other two she will draw an annual total net rental of about £50. He expresses his opinion that certainly the money could not have been expended to greater advantage. Mrs. Anderson also writes to convey her sincere thanks to Lord Stamford and his committee for their sympathy shown in the trouble they have taken, and her deep sense of gratitude to the subscribers and to the proprietors of the medical journals for the great help they have given which has relieved her of intense anxiety as to the future of her sons.

SYPHILIS AS A CAUSE OF FRIEDREICH'S DISEASE AND ALLIED NERVOUS AFFECTIONS.

AN interesting contribution on the etiology and symptoms of Friedreich's disease and allied nervous affections of the class known as "family paralyses"—that is, paralyses affecting more than one child of the same family—is published by Dr. A. Bayet in the *Journal de Neurologie* of April 20th last. Dr. Bayet deals at length with the symptoms and clinical histories of five patients and points out clearly the action of inherited syphilis as a potent cause in the production of these grave nervous affections. Two of the patients were boys, aged nine and 17 years respectively, and three were girls, aged nine, 11, and 14 years respectively. The youngest girl was one of twins, her twin sister having died from some obscure nervous affection. These five patients suffered either from the well-known symptoms of Friedreich's disease with corresponding defect of mental development or from cerebellar ataxy approximating to the "hereditary" type described by Pierre Marie.

They also presented a variety of signs which were regarded as conclusive evidence of inherited syphilis—viz., cicatrices about the mouth and lips the result of rhagades, corneal opacities from interstitial keratitis, "geographical tongue," and in two cases the formation of gummatous ulcers of the tonsil and ankle respectively. These two cases of gummatous ulcer responded well to treatment with alkaline iodides. It was thus clear, says Dr. Bayet, that syphilis inherited from the parents acted deleteriously on the growing nervous systems of the offspring, producing arrest of development of the neurons or nerve-cells of the cerebellum chiefly, but also of the cerebrum, so that the ataxy was accompanied by mental defect.

WHOSE BUSINESS?

AT the meeting of the Bath Board of Guardians held on April 30th a letter was read from the medical officer of the workhouse infirmary stating that on April 9th the supervision of the infirmary wards was taken out of the hands of the superintendent nurse and transferred to the master and matron of the workhouse on the ground that such supervision was not included in the words of the General Order of the Local Government Board, August 6th, 1897—viz., "in all matters of treatment of the sick." The medical officer added that he held exactly the opposite view, that the cleanliness of the wards was embodied in matters of treatment of the sick, an opinion with which most people certainly will agree.

CHOLERA AT EL TOR.

OUR correspondent in Egypt writes: "12 different steamers have arrived at El Tor from Jeddah with cholera on board and by the last weekly return it appears that 51 cases have been found on these steamers, while of this number 38 are already dead and 13 remain under treatment in the quarantine camp hospitals. It is satisfactory to find that only one case of cholera has been reported from Jeddah during the week ending May 3rd. Those of the pilgrims who have satisfactorily purged their quarantine are now beginning to pass through the Suez Canal and the Egyptian passengers are permitted to land at Suez."

THE ITALIAN HOSPITAL BALL.

THE annual ball in aid of the Italian Hospital, which was omitted last year through respect for the memory of the late Queen, was held on May 6th in Prince's Hall, Piccadilly, and proved to be even a greater success than on any former occasion. Nearly 700 guests were present, including the Italian Ambassador (President of the hospital) and Madame Panza, the Lord Mayor and Lady Mayoress, the Austrian Ambassador and Countess Deym, the Swiss Minister (M. Bourcart), Madame Ortelli (widow of the founder of the hospital), and representatives of the German and other embassies. Amongst the members of the honorary medical staff, to whose efforts the success attained was in a large measure due, there were present Sir Dyce Duckworth, Cavaliere J. C. F. Naumann, Cavaliere Distin Maddick, Dr. J. Donelan, Dr. T. V. Dickinson, Dr. J. P. Henry, and Cavaliere J. FitzGerald.

PETROLEUM LAMP ACCIDENTS.

RECENT fires in London having their origin in accidents with petroleum lamps have once more led to some interrogation of the Home Secretary on the subject. Mr. Ritchie could not promise any decided action in the matter, pointing out that the report of a Select Committee published in 1898 threw very grave doubt upon the idea that raising the flash-point by legislation would prevent lamp accidents. We are still of the opinion, based upon our own practical inquiries on the subject, that these accidents arise from the use of grossly defective and ridiculously low-priced lamps rather than from so-called low-flash oil, and that the only remedy will be to stop the sale of such lamps. There are immense practical and scientific difficulties in the way which render any legislation with regard to the flash-point of the oil hardly possible.

THE PREVALENCE OF SMALL-POX.

ON Saturday, May 10th, 25 cases were admitted to the hospitals of the Metropolitan Asylums Board; on Sunday, the 11th, 30 cases were received; on Monday, the 12th, there were 24 admissions; on Tuesday, the 13th, 26 fresh cases; and on Wednesday, the 14th, 23 cases were notified. In the county of Essex for the week ending May 10th 46 new cases were notified.

THE MEDICAL, SURGICAL, AND HYGIENIC EXHIBITION.

THE sixth annual Medical, Surgical, and Hygienic Exhibition will be held at the Queen's Hall on May 20th, 21st, 22nd, and 23rd from 1 P.M. to 10 P.M. A concert by a select orchestra will be rendered each afternoon from 3 to 6 and in the evening from 7 to 10. We are informed by the secretary that there will be many novelties shown which are likely to interest the medical profession.

"THE DANGEROUSLY INFLAMMABLE NATURE OF CELLULOID."[1]

WE are glad to note that a question was asked in the House of Lords on Monday as to whether some restrictions could not be placed upon the sale of celluloid, but the answer was decidedly disappointing. Lord Saltoun, who asked the question, referred to our own inquiries on the subject as well as to an original contribution printed in our columns two months ago. More than four years ago we abundantly demonstrated by practical experiments the dangerously inflammable nature of celluloid, and we suggested that the manufacturers of celluloid articles should be compelled to stamp plainly upon them the words "highly inflammable." Speaking on behalf of the Government Lord Belper said that the Secretary of State did not see his way to interfere by legislation with the sale of celluloid. Lord Belper made an extraordinary statement when he said that if properly manufactured and free from impurities celluloid would not take fire. Celluloid is celluloid, and celluloid is by its nature highly inflammable, just as gunpowder is.

THE HEREDITY OF POETS.

As already noted in THE LANCET of May 10th, p. 1337, Möbius has, to the best of his belief, proved that poetic talent is in all cases traceable to the mother of the bard. The touch of sentiment in this position wins it ready acceptance. It is a feminine doctrine, the obvious inference from which is that the rougher sex is not apt to beget those gentle beings, the poets. Francis Galton, however, in "Hereditary Genius" (1869) has stated positively "in the case of poets and artists, the influence of the female line is enormously less than the male," and he supports his assertion with a "summary of relationships of 24 poets grouped into 20 families." From this it would appear that Goethe alone can trace poetic talent to his mother. "From my father," he says, "I inherit my frame and the steady guidance of my life; from dear little mother (Mütterchen) my happy disposition and love of story-telling (fabuliren)." Byron's mother is described as "strange, proud, passionate, and half-mad," and Tasso's as gifted in all respects. The other poets mentioned by Galton have some of them gifted fathers, as Milton; others gifted uncles and other relatives, mostly, alas, males. There are families in which literary and other talent is hereditary, as, for instance, the families of Coleridge and Wordsworth; but, as a rule, the sons of poets are dull dogs. The late Sir Percy Shelley should have been a paragon to judge by his ancestry, a poet father and a mother who wrote "Frankenstein." Sir Percy Shelley, however, was content to win only social popularity as an organiser of private theatricals. The son of the poetic Brownings is a meritorious painter—not a poet—and the descendants of certain other famous poetic marriages are, alas, in lunatic asylums. We have in mind three insane descendants of famous poets. It is possible that the children of poets are bored in early years by their surroundings and the mental attitude of their parents and make haste to become prosaic. Certain it is that the sons of political reformers and enthusiasts are often the most unprogressive of men, the sons of millionaires the least businesslike, and those of divines the least saintly.

---

[1] THE LANCET, Feb. 22nd, 1902, p. 540.

THE annual meeting of the Association of Asylum Workers will be held on Thursday, May 22nd, 1902, at the Medical Society's House, 11, Chandos-street, Cavendish square, W., at 4 P.M., Sir James Crichton Browne in the chair. A presentation will be made of two gold and two silver medals awarded by the association for long and meritorious nursing service and all interested in asylum work and workers are cordially invited to attend. Communications should be addressed to Dr. G. E. Shuttleworth of Ancaster House, Richmond Hill, Surrey, the honorary secretary of the association.

A CONVERSAZIONE of the Medical Society of London will be held in the rooms of the Society, 11, Chandos-street, Cavendish-square, W., on Monday, May 26th. The reception by the President is fixed for 8.30 P.M., and an Oration by Dr. Stephen Mackenzie will be given at 8.45 P.M. There will also be an exhibition of drawings and etchings of London and its vicinity, and music will be rendered by the Bijou Orchestra, when smoking will be *en règle.*

THE festival dinner of the Medical Graduates' College and Polyclinic will take place at the Criterion Restaurant on Thursday, June 5th. The Right Hon. H. H. Asquith will take the chair and will be supported by many well-known men, medical and lay, as stewards. Communications should be addressed to the secretary of the Dinner Committee at the College, 22, Chenies-street, Gower-street, W.C.

THE King has sanctioned the following promotions and appointments to the Order of the Hospital of St. John of Jerusalem in England: Mr. Robert Brudenell Carter, F.R.C.S. Eng., from Knight of Grace to Knight of Justice, and Mr. Robert Fraser Calder Leith, M.B, F.R C.P. Edin., and Sir William Henry Bennett, K.C.V.O., F.R C.S Eng, to be Knights of Grace.

A DINNER of the present and past students and officials in connexion with the West London Hospital Post-Graduate College will take place on Wednesday, June 11th, 1902, at the Empire Rooms of the Trocadéro Restaurant, London, at 7.30 P.M. Mr. H. Percy Dunn will take the chair and communications should be addressed to Mr. L. A. Bidwell.

THE Glasgow University Club, London, will, on Tuesday, July 1st, give a dinner in honour of the Coronation in the Trocadero Restaurant, Piccadilly Circus. The Very Rev. Dr. Story, Principal of the University of Glasgow, has promised to preside. Particulars can be obtained from Dr. C. O. Hawthorne, 28, Weymouth-street, Portland-place, W.

THE opening lecture of the summer course at Brompton Hospital for Consumption and Diseases of the Chest will be delivered on Wednesday, May 21st, at 4 P.M., by Dr. T. Henry Green. The subject of the lecture will be Difficulties in the Recognition of Pulmonary Tuberculosis.

DR. J. ROSE BRADFORD, F.R.S., will give an address at a meeting of the University College Medical Society, on Wednesday, May 21st, on the Relation of Biology to Medicine. The chair will be taken by Mr. Victor Horsley at 8.30 P.M.

MR. THOMAS JOSEPH STAFFORD, F.R.C.S. Irel., has been appointed by the King a member of the Royal Commission on Sewage Disposal, in the room of Mr. Charles Philip Cotton, resigned.

UNIVERSITY COLLEGE, LONDON: APPEAL FOR THE EQUIPMENT AND ENDOWMENT OF ADVANCED UNIVERSITY EDUCATION AND RESEARCH.

ON May 9th in the Egyptian Hall of the Mansion House a meeting was held under the presidency of the Lord Mayor of London in support of the fund for advanced university education and research in connexion with University College, London. The following are the purposes for which funds are required:—

> (a) For extension of buildings and laboratories to provide adequate accommodation for teaching and research in such important departments as modern languages, chemistry in all its branches, geology, physiology, pathology, bacteriology, botany, engineering in all its branches, advanced medical studies, &c., £250,000; (b) for maintenance and laboratory expenses an annual endowment of £6000, or a capital sum of £200,000; (c) for endowment of professorships and lectureships an annual endowment of £20,000, or a capital sum of £700,000. The total sum required is therefore £1,150,000.

The LORD MAYOR, in opening the proceedings, said that the occasion of the meeting was unique. Never before had the City been asked for such a large sum of money for the furtherance of education and research in London. Every day the struggle for commercial supremacy became more severe and the fact could not be disguised that commercial supremacy would follow intellectual supremacy. University College was the only institution that had declared itself ready to be incorporated with the University of London and the result of this appeal would be to help the University of London itself. He earnestly urged the citizens of London to subscribe largely to the fund.

The Duke of DEVONSHIRE proposed the following motion:—

> That this meeting is of opinion that the incorporation of University College, London, in the University of London will materially promote higher education and research in London, and that, with this object, a fund should be raised to equip and endow the College adequately for such education and research.

After referring to the University Commission Bill of 189 the result of which was to give to the University of Lond teaching powers and a controlling influence over the vario schools which were then federated in the University, so th a course of instruction might be adopted fitted to the nee of the great modern metropolis, he urged that in a professions and industries success must be dependent c a knowledge of scientific principles and on the traine capacity to apply those principles. Universities, he sai were no longer a necessity for one class alone, but the welfa of the whole nation demanded that they should seek fro all classes men of high intelligence and equip them with th highest training. As a nation we could not be said to have rec gnised the necessity of corresponding changes in our highe university training. The older Universities of Oxford an Cambridge had recognised the necessity and had made grea efforts to equip themselves with the necessary machinery but they had found themselves hampered by a want c the necessary resources. Speaking for the University c Cambridge, of which he was Chancellor, he assured hi hearers that his university had no intention of abandonin its place in the front rank which it held as a centre c teaching and research Our success as a nation depende upon the number of trained brains which were produced, bu the older universities could not supply the number of traine men required for our national industries. In London th university movement had up to the present time failed to receive that support which might be expected from the wealthiest city in the world. But now there was an opportunity afforded to the citizens to repair any past neglect and to create for London a university that would be worthy of the capital of the Empire and adapted to the special needs of the metropolis of the Empire. Before the proposed incorporation could take place certain preliminary conditions were required. The first was the extinction of the debt upon University College which had been accomplished by a gift of £30,000 from the Drapers' Company. The second was the removal of the University College School, an institution of a secondary type, in order to obtain the needful accommodation for university teaching and research. The third was an arrangement by which separate provision could be made for advanced medical studies so as to place the school of medicine on a proper footing The estimated cost was £100,000 and that was the immediate object of the appeal Of this sum £30,000 had been given by an anonymous donor and other sums were promised amounting to £15,000 Two great objects would be gained by the success of the appeal. First, a fuller utilisation of the resources of the College as an establishment for the promotion of advanced studies and, secondly, the provision for the University, which had as yet done little but create administrative machinery, of the means of entering properly equipped upon a twofold mission of instruction and research.

Sir Michael Foster, M.P., who seconded the motion, said that the purse of London was big enough to help not only the University of London but the older universities as well. There ought to be in the very heart of London a real and effective university. The incorporation of University College with the University of London would benefit the people of London whatever might be their calling

Professor A. W. Rücker, in supporting the motion, said that for many years he had taken an active share in higher education in London and he firmly believed that the question as to whether the development of the University of London was to take place along simple and most useful lines or whether it was to be carried out by a number of awkward and ill-fitting compromises depended entirely upon the success of the scheme of incorporation.

The motion was then carried unanimously.

Lord Brassey moved :—

That this meeting urges on the citizens of London the importance of giving a generous response to the appeal now made for £1,000,000 to equip and endow University College, London.

Lord Avebury seconded the motion.

Mr. Lionel Phillips, in supporting the motion, said that his firm would subscribe £10,000 to the present fund and reserve a larger donation for the future when he hoped a more extensive scheme would be brought forward Much had to be done if the higher education in this country was to be put on a footing with that of America and Germany.

Mr. H. R. Beeton said that upon the progress of science and invention depended the better feeding of a people.

Captain Jessel, M P, also supported the motion, which was carried unanimously.

Sir Richard Farrant (treasurer of the Fund Committee) said that although scarcely four weeks had passed since the appeal for funds had been made subscriptions amounting to over £110,000 had already been received This sum included donations of "at least" £30,000 through Sir Michael Foster from "A Former Student" and £30,000 from the Drapers' Company.

On the motion of Lord Reay, seconded by Mr A. Prevost (Governor of the Bank of England), a vote of thanks was accorded to the Lord Mayor and the proceedings terminated.

THE METROPOLITAN WATER-SUPPLY: THE LONDON WATER BILL.

The Lancet of May 3rd, p. 1274, contained a brief account of the proceedings of the Joint Committee of the two Houses of Parliament appointed to inquire into the London Water Bill. At the sitting of April 30th the committee decided to alter entirely the constitution of the proposed Water Board by withdrawing from the metropolitan boroughs and from the urban districts the representative powers which the Government Bill proposed should be conferred upon them The immediate result of this decision has been already referred to in a leading article which appeared on May 10th, p. 1333. At the commencement of the tenth sitting of the committee Mr J. D FitzGerald made a short statement on behalf not of the Local Government Board as Lord Balfour of Burleigh interrogatively suggested, but of the Government. Counsel then mentioned the points which had led the Government to decide as to the composition of the Water Board which it proposed and asked the committee to receive evidence on the question with a view to reversing the decision to which the committee had arrived. Counsel representing the City of Westminster supported this application and the committee resolved "by a majority" to receive the evidence on behalf of the metropolitan boroughs and the urban districts outside the metropolis should they think fit to tender it. It was then pointed out by Mr FitzGerald on the part of the Government, that many of the urban districts and metropolitan boroughs had not petitioned because they were satisfied with the provisions contained in the Bill. Lord Balfour of Burleigh pointed out that as the committee had power to send for persons and papers there would be no technical difficulty in the matter of calling witnesses and that no question of *locus* need arise

Seven witnesses were heard at this sitting The first called was Mr. William John Crump, Justice of the Peace for the county of Middlesex and Mayor of Islington, who stated that when the municipal authorities of that borough heard that the Government was about to introduce a Bill creating a Water Board a resolution was almost unanimously carried requesting that a representation should be made to the Local Government Board to the effect that the borough councils should be represented on the board on the ground that they were the health authorities.

Mr. James White, mayor of the Borough of Lambeth gave evidence to the effect that a majority of the borough council which he represented had passed a resolution in favour of the Bill in the form in which it was originally introduced into Parliament.

Mr Charles Wilson, clerk to the Urban District Council of East Ham, stated that the district in which he was employed had increased enormously in population during recent years The council was, of course, the sanitary authority for the district, which was in the area of the Essex County Council. He contended that the County Council did not properly represent the local urban authorities and that the latter were always complaining about it. The Essex County Council had so many rural members that as a matter of fact the urban population of East Ham—chiefly a working-class population—strongly felt that their rights were not properly looked after. For these reasons they contended that they ought to be represented on the Water Board

Mr. Edmund Barnes, mayor of St. Pancras, stated that the borough council of that town had considered the Government Bill when it was originally deposited and had passed a resolution in favour of the measure, and he believed that the council was of the same opinion still

Colonel Clifford Probyn, mayor of the City of Westminster, said that the Bill had been considered by the Law and Parliamentary Committee of the Westminster Council, and that that council, without committing itself to the details of the Bill, strongly approved the proposal to establish a Water Board of members to be appointed by the metropolitan boroughs and by certain other public bodies. The borough councils were the sanitary authorities and were brought much more closely in touch with water consumers than was the case with the London County Council.

Mr Hamilton Benn, mayor of Greenwich, said briefly that, as representing the borough council of Greenwich, he distinctly desired that they should be represented on the Water Board and he would regret any decision which would deprive the metropolitan boroughs of such representation The Greenwich Borough Council had passed a resolution to the effect that they ought to be represented on any water trust which might be formed.

Mr T. W. Williams, the mayor of Lewisham, said that the borough council of which he was the representative had passed a resolution approving the principle of the Bill so far as representation was concerned

At the eleventh sitting of the committee no less than 27 witnesses were examined.

Sir John Aird, M.P., gave evidence on behalf of Paddington, of which borough he is mayor. He stated that for the sake of that place it was important that they should be represented on the Water Board.

Mr. **WALTER JOHNSON**, mayor of Hackney, read a resolution passed by a committee of the council of that borough. It was somewhat long, but the most important part was to the effect that the council approved the Bill but that the borough of Hackney ought to have two representatives instead of only one on the Water Board. A public meeting was held at Hackney and a resolution was passed not in accordance with the mayor's views. The meeting protested against the proposal to hand over the vast interests of London in its water-supply to "an irresponsible authority on the discredited model of the Metropolitan Board of Works."

It is impossible in the space at our disposal to give a digest of all the evidence tendered, but the committee has at any rate been the means of bringing out a good deal of information which cannot fail to convince those who heard it that the opinion of the London sanitary authorities cannot be entirely ignored.

On May 12th the committee had a prolonged private sitting to decide as to what course it should take in regard to its decision of April 30th. The result of its deliberations was announced by Lord **BALFOUR** of **BURLEIGH**. It appears in effect to be that the schedule which was "referred back" to those in charge of the Bill will remain at present as part of the Bill and the details of the schedule will be considered when the Bill is examined clause by clause. The announcement made by Lord Balfour of Burleigh was that a motion had been brought forward at the private sitting of the committee to the effect that it should adhere to its resolution of April 30th. This motion was lost. There had been an equal number for and against the motion. The rules in force in the House of Lords governed committees. The rule was that in a case of equality of votes (if in the case of a committee everybody was present) the form of the Bill would stand. In this case the form of Schedule III. would be considered by the committee when it reached that point in the Bill after going through the previous clauses. The procedure adopted by the committee was arranged according to precedent and Lord **BALFOUR** of **BURLEIGH** announced that when the schedule was reached in the way indicated it was possible that a full statement might be made of the effects of the procedure on an amendment which might be moved.

After this announcement the committee proceeded to go through the Bill by clauses and certain amendments proposed to it by the water companies. On the request of counsel for the Local Government Board an adjournment was made to enable the Board to get up its case against the water companies' amendments.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

ANNUAL GENERAL MEETING.

*DR. G. A. **HERON** took the chair at the annual general meeting of the London and Counties Medical Protection Society on May 8th, at their new offices, 31, Craven-street, Strand, London, W.C.*

The annual report stated, that the society maintained a healthy increase in numbers and usefulness. Its growth naturally had brought with it increased responsibilities and expenses, but the latter appeared to retain a just proportion to the number of members. A member had to complain to the society of a deliberate and groundless slander, maliciously put in circulation aginst him by a former patient. The offender had thought it more prudent to settle the matter by publicly apologising, and paying the sum of £10 to a charity, than to face the consequences of the legal action commenced against him. There had been a number of cases in which patients had sought to evade payment by alleging want of skill on the part of their medical advisers; and in connexion with that subject the council, in order to prevent waste of time of the society's officials, wished to remind members that it was no part of the scope of the society to collect professional debts for members, where no charge was made against them, and where no principle of great importance to the profession generally was involved. Many difficult matters had been occupying the energies of the society during the year in reference to medical aid and friendly societies, and their medical officers. Several registered dentists had been summoned before the General Medical Council for issuing objectionable advertisements, and they had been leniently dealt with on promising not to offend again. In respect to the outbreak of small-pox, the society had had, on the one hand, to defend a member, who had been prosecuted by a metropolitan borough council, for not notifying as small-pox a case he believed at the time he saw it to be chicken-pox; and, on the other hand, members from whom damages had been claimed, because they had notified as small-pox cases subsequently declared not to be suffering from that disease. The report added, that all the cases were successfully defended. The society was in a sound financial condition, the surplus funds amounting to £1794.

Dr. **HERON** moved the adoption of the report, and said that a certain well-known utterance of Mr. Joseph Chamberlain in the House of Commons, would not have been delivered if the medical profession were not politically impotent. Concerning the prosecution of quacks he said, that unless the society were prepared to spend enormous sums of money in legal proceedings they had better let them alone. The law, for some reason which he did not understand, seemed to favour the quacks. If the medical profession were politically powerful they might hope, at some distant date, to have that altered. He was not inclined to sympathise with the public when they complained of quacks. It occurred to him when he read of the atrocious way in which people allowed themselves to be gulled that, to use a schoolboy phrase, "it served them right." The obvious advantage of belonging to a society like theirs was so clear, that he confessed it seemed to him deplorable, that at the present moment there should be in the medical press requests made for subscriptions to aid a gentleman who had been loaded with heavy legal costs, after successfully defending an action at law which ought never to have been brought into court. It was the duty of every medical man to belong to a society for medical protection. The financial position of the London and Counties Medical Protection Society was sound enough to appeal to the common sense of every reasonable man in the medical profession; and if anyone hesitated to join the society, and one day became involved in a lawsuit, then he thought he would have only himself to blame because he ought to have protected himself against such a risk.

The motion, having been duly seconded, was carried unanimously.

Dr. W. G. **DICKINSON** suggested that the annual report might be issued in a somewhat different form, and he advocated a fuller and more complete account of the cases dealt with by the society.

The meeting terminated after re-electing the council and officers.

THE ROYAL SOCIETY CONVERSAZIONE.

A VERY interesting and attractive series of experiments, illustrations, and specimens was presented to the view of the Fellows and their friends at the annual conversazione of the Royal Society which was held at Burlington House on May 14th, but it cannot be said that any particularly brilliant or epoch-making demonstration was given. Contrary to expectation, no illustrations were given of that remarkable property of certain elements, radio-activity, which has been so much discussed of late. Electrical phenomena held the first place and attention seems to have been particularly directed to the physical characteristics and properties of ultra-violet light.

Professor J. A. Fleming, for instance, showed an exceedingly interesting experiment illustrating the effect of ultra-violet light on the electric discharge. The action of the ultra-violet light emitted from the edge of the coating of a Leyden jar upon the spark of an induction coil charging it was shown. The jar is arranged between two "spark gaps" in parallel, one larger than the other and both connected with the terminals of an induction coil. The jar is placed nearest to the shorter gap; the spark then happens always at this gap. If a plate of mica or glass, which are very opague to ultra-violet rays, be interposed between the jar and the active gap a spark at once appears at the other gap. It was shown that this spark can be quenched by illuminating the first or shorter gap with ultra-violet light from burning magnesium or a naked electric arc and this can be done from considerable distances. Hence the idea arises that the effect might be utilised for telegraph purposes without wires. Dealing with a similar phenomenon Dr. Dawson Turner showed in another exhibit that the ultra-violet radiation of a condenser spark will discharge an electrified body whether positively or negatively charged.

Of the various substances which have been tried rock salt seems to be the most transparent to ultra-violet radiations. Mr. Mackenzie Davidson, besides exhibiting some most realistic x-ray photographic effects, both by transparencies and negatives shown in a Wheatstone stereoscope, also demonstrated the remarkable fact that if an ordinary photographic plate be exposed to x-rays and then to ordinary diffused active light a reversed negative is obtained on development in bright white light. Plates were thus developed at intervals during the evening Mr. A. C. Cossor exhibited a new therapeutic x-ray tube which is worthy of notice. It is so designed as to constitute an x-ray "applicator," the rays passing through a certain area which varies in different tubes according to the size of the diseased part which it is desired to submit to treatment. Mr W. R. Pidgeon exhibited a new electrical influence machine suitable for x-ray work in camp in countries where the heat makes it difficult to preserve induction coils. The sectors being imbedded in a vulcanite-like substance called "volenite" and no glass or wax being used in the machine, it is not liable to damage and its efficiency is unimpaired by rough usage. Professor W. Ramsay showed the spectra of krypton and neon, the colour of the former tube when the discharge passes being regarded by many persons as lilac and by others as green. Professor Ramsay thinks this phenomenon "is conditioned by the size of the yellow spot on the retina." The wearing of glasses changes the colour to some persons, but to others it makes no difference. The spectrum of krypton is characterised by a brilliant yellow and a brilliant green flame with some lines in the deep blue and violet. Sir Norman Lockyer lent a very interesting series of photographs of metallic spark spectra in air and water. A similar subject was illustrated by Professor A Schuster who was able to produce the spectrum of iron in the flame of the Bunsen burners. The method consisted in mixing a spray of the solution of an iron salt with the air introduced into the burner. With large dispersion a considerable number of lines appear seemingly identical with those of the arc spectrum. The process of natural colour photography based upon Young's theory of trichomatic vision was demonstrated in a beautiful series of natural colour photographs exhibited by Messrs Sanger, Shepherd, and Co. Cameras for the process were shown. Negatives or colour records of the object are taken through colour filters admitting light of the three primary sensations—red, green, and blue-violet—in accordance with the power of the respective sensations to excite the eye. From the three negatives three coloured positives are printed upon a special film which when superimposed exactly reproduce the form and colour of the object photographed. Some of the effects obtained were projected upon the screen during the evening by means of the electric lantern with strikingly beautiful results

Some of the exhibits were decidedly chemical in character Such, for example, was the series of fabrics dyed with synthetic indigo and shown by the Badische Anilin- und Soda-Fabrik, Ludwigshafen. Specimens of the raw material napthalene and the intermediate products formed were shown. It is apparently identical with natural indigo and it is curious that the last stage in the process, whether the starting point be napthalene or the indigo plant, is identical—viz., the oxidation of indoxyl into indigo. Opposite to this exhibit Mr. W. Rosenhain showed an improved form of Thompson Coal Calorimeter, The method consists in burning the coal in a stream of oxygen in a closed vessel water-jacketed The apparatus is so constructed as to be easily manipulated and to secure complete combustion and the complete transference of the heat to the water of the calorimeter The ignition is started by electric current. The process is of importance in determining the calorific value of fuel.

Professor Wyndham Dunstan exhibited a very interesting series of poisonous fodder plants and food grains and their cyano-genetic glucosides. We have already referred in our columns to the production of hydrocyanic acid from the *Lotus Arabicus*, which grows on the banks of the Nile. The young plant contains a glucoside, lotusin, from which prussic acid is formed and at this stage it is highly poisonous to cattle.

Mr. A. Vernon Harcourt, F.R S, exhibited an apparatus by means of which any desired proportion of air and chloroform could be mixed. The apparatus has already been described in THE LANCET.

Professor Silvanus P. Thompson exhibited the first folio Latin edition of *De Magnete* (London, 1600), the author of which was Dr. William Gilbert who was born in Colchester in 1540 and who died in 1603. He was President of the Royal College of Physicians and body-physician to Queen Elizabeth Other editions of the same work were also shown, the whole forming a valuable and interesting collection.

Mr. J. Gray, B.Sc., exhibited some ingenious instruments designed especially for measuring and taking contours of the living head. The method is well adapted for showing cephalograms of different races. Dr. C. A. McMunn illustrated the spectrum of zircon and he also exhibited spongioporphyrin, the colouring matter of a certain Australian sponge, which is very remarkable in giving an absorption spectrum recalling that of oxy-hæmoglobin and of turacin.

The Marine Biological Association had an exhibit illustrating the manner in which the scales of fishes are an index of age. The scales of many fishes show a series of parallel eccentric lines which indicate successive increments of growth. Annual rings may be detected which indicate the age of the fish in years Tropical medicine was represented in two exhibits by Lieutenant-Colonel D Bruce, F.R.S., and Dr. Joseph Everett Dutton, respectively. The former showed a new species of parasite (*Trypanosoma Theileri*), discovered in the blood of cattle in South Africa. It infects cattle but not horses or dogs, and is easily distinguished from the tsetse fly. Dr. Dutton showed a specimen of trypanosoma found in the blood of a man. The presence of the parasite was associated with symptoms closely resembling those occurring in animals suffering from tsetse fly disease. Mr. W E. Hoyle exhibited specimens of a Mediterranean cephalopod possessing luminous organs, the most striking feature of which is that they are concealed by the integument and are only effective by reason of its transparence in the living condition.

Looking Back.

FROM

THE LANCET, *SATURDAY, MAY 15*, 1824.

Foreign Department.

(From the Gazette de Santé, April 16.)

ANTIDOTE AGAINST CORROSIVE SUBLIMATE.

We stated some time ago that M. SADDEI had detected in gluten, the property of decomposing the deuto chlorate of mercury. An Italian Journal records a case of the efficacy of this antidote. A medical pupil swallowed seven grains of corrosive sublimate, supposing it to be calomel. The effects of the poison soon manifested themselves. The emulsive powder of gluten was administered according to the method suggested by M. SADDEI, the sublimate was decomposed, and evacuated by vomiting

M. VIREY has an article in the *Journal de Pharmacie*, on the poison called woorara. It is probable that few persons are acquainted with it in France; it is, however, much employed in America where the savages of the Guiana arm the points of their arrows with it. The monkeys, and other animals wounded by these poisoned arrows, fall into violent convulsions, which shews that the poison acts principally on the nervous system; nevertheless the savages eat it without being incommoded by it. It is not known from what vegetables the woorara is extracted; Barcroft and other travellers say that it is taken from a plant of a climbing species; M. Virey thinks it not impossible that the poisonous juice of the *cerbera* may be used in it. What is of more importance, however, is a remark which has been for some time made, namely, that the plants cultivated in gardens for the purposes of medicine, have undergone a sensible diminution in the strength of their properties. This circumstance should induce us to procure them in their wild state whenever we can do so, for they grow in soils less rich, less sheltered, and less likely to fill them with inert juices An instance of this kind has been observed in the *hyosciamus* *niger* by M. Ricken, Chemist at Wittand. This plant cultivated gives an extract almost inert; while in its wild state it gives a much stronger extract. This is a very material circumstance in the practice of medicine, and may account for a number of anomalies and discrepancies in the results obtained by different practitioners.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary meeting of the Comitia was held on May 8th, Sir WILLIAM SELBY CHURCH, Bart., the President, being in the chair.

The following Members who had been duly elected at the last meeting were admitted as Fellows:—

Dr. Frank Montague Pope, Dr. Edward Malins, Dr. William Alfred Wills, Dr. Thomas Hancock Arnold Chaplin, Dr. William Page May, Dr. Arthur George Phear, Dr. George Francis Blacker, Dr. John Fawcett, Dr. Herbert Campbell Thomson, Dr. Albert Sidney Frankau Grünbaum, Dr. James Barr, and Dr. Joseph John Perkins.

The following communications were received: 1. From the secretary of the Brussels International Conference on the Prevention of Syphilis, praying the College to reconsider its resolution not to send a delegate. It was resolved:

> That the College should accede to the request and that the choice of a delegate should be left to the President.

2. From the secretary of the Jenner Institute, stating that the annual general meeting will be held on June 30th; also that Dr. J. F. Payne retires by rotation from the Council and requesting the College to appoint a representative for the ensuing year. Dr. Payne not wishing to be re-elected the nomination was left in the hands of the President.

The REGISTRAR (Dr. E. Liveing) proposed, and the Senior Censor (Dr. T. T. Whipham) seconded, the enactment for the first time of the following by-law:

> That Dr. Henry Carr Maudsley and Dr. William Camac Wilkinson, elected Fellows on April 24th, being resident in Australia, be admitted *in absentiâ*, any by-law to the contrary notwithstanding.

This was adopted.

The PRESIDENT then dissolved the Comitia.

THE CASE OF DR. W. T. LAW.

DR. J. G. GLOVER presided at a meeting of the members of the medical profession on May 9th in the Throne Room, Holborn Restaurant, London, W.C., held for the purpose of expressing sympathy with Dr. W. T. Law in connexion with a case in the law courts recently decided in his favour but in which his expenses amounted to some £700.

Dr. GLOVER commented on the smallness of the meeting, but added that fortunately several members of the profession had already sent substantial proofs of their sympathy. They had not met, he said, to discuss the treatment of asthma or the proper attitude of medical men towards a neurotic and asthmatic patient, but to express sympathy with Dr Law. One good purpose of such a trial as that to which Dr. Law had been subjected was to give strong proof of the oneness of the medical profession; to show that when one member suffers the others sympathise. Their help, he added, should be efficient and prompt, as Dr. Law's expenses would reach the large sum of £700. It was a satisfactory proof of the sympathy and solidarity of the medical profession that promises of generous subscriptions had come in from all parts of the United Kingdom and from every class of the profession. Dr. Glover concluded by calling upon Dr. Theodore Williams who, he said, had done yeoman service in this cause, to propose the first motion.

Dr. R. PARAMORE, who had convened the meeting, having stated that he had received subscriptions amounting to over £360, Dr. THEODORE WILLIAMS moved:—

> That this meeting begs to express its sympathy with Dr. Law in reference to the recent unjust action against him in the case of Forsythe *v.* Law; and its determination to do what it can to give that sympathy a practical form.

Dr. Williams concluded a very able statement of the facts of the case by proving that Dr. Law was perfectly innocent and that it had been shown that he had conducted himself in the strictest professional manner possible. He was glad to say from inquiries which he had made that a large number of the members of the medical profession had expressed their willingness to subscribe towards the fund in aid of defraying the expenses incurred.

The motion was carried unanimously.

The following motions were also passed:—

> That this meeting expresses its thanks to Dr. Paramore for his active efforts in initiating this movement for the payment of Dr. Law's expenses and congratulates him on the measure of success already obtained.
>
> That the President of the Royal College of Physicians of London, the President of the Royal College of Surgeons of England, the Master of the Apothecaries' Society, and the editors of the metropolitan medical journals be requested to act, with Dr. Paramore, as trustees of the fund now being raised at his instance for the payment of Dr. Law's heavy expenses in respect of his defence in the case of Forsythe *v.* Law.

This last motion was proposed by Dr. GLOVER.

The meeting closed with resolutions of thanks to Dr. Glover for presiding and to the proprietors of the Holborn Restaurant for allowing the use of the Throne Room for the purposes of the meeting.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on May 8th, the President, Mr. HENRY G. HOWSE, being in the chair.

Dr. GEORGE BAGOT FERGUSON was introduced and was admitted a Fellow of the College.

The SECRETARY reported the illness of Professor Stewart, conservator of the museum, and leave of absence was granted to him.

The PRESIDENT reported that he had accepted on behalf of the Council a portrait by C. R. Leslie, R.A., of Benjamin Travers, F.R.S., Sergeant-Surgeon to Queen Victoria and President of the College in 1847 and 1856, the portrait having been offered to the College by Dr. Llewellyn Morgan, executor of the late Miss Travers.

The best thanks of the Council were voted to Dr. Morgan for the gift.

A letter was read from Surgeon-General A. F. Bradshaw, C.B., honorary secretary to the Oxford Eye Hospital, stating that it is proposed to found in the University of Oxford a Readership in Ophthalmology, to be held in conjunction with the honorary surgeoncy to the Oxford Eye Hospital, and asking the College to allow its president to be an *ex-officio* member of a standing board for future elections to the combined appointments.

The Council agreed to this request.

A letter was read from Dr. FREDERICK J. SMITH, F.R.C.P. Lond., F.R.C.S. Eng., President of the Association of Licentiates of the Royal College of Physicians of London and Members of the Royal College of Surgeons of England, calling attention to a petition which has been signed by several hundreds of Licentiates and Members, and asking leave to present the petition by deputation.

A committee of the Council was appointed to receive the deputation.

Mr. A. WILLETT moved:—

> That a committee be appointed to consider and report whether the time has not come for the two Royal Colleges by joint action to take such steps as may seem advisable for entering into combination with the University of London for a scheme of common examination for the degree of M.B. of the University and for the qualification of L.R.C.P. Lond. and M.R.C.S. Eng.

A committee was appointed for this purpose.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8602 births and 4894 deaths were registered during the week ending May 10th. The annual rate of mortality in these towns, which had been 18·3, 17·0, and 16·6 per 1000 in the three preceding weeks, rose again last week to 17·2 per 1000. In London the death-rate was 16·6 per 1000, while it averaged 17·4 in the 75 other large towns. The lowest death-rates in these towns were 7·5 in East Ham, 8·5 in Reading, 8·6 in King's Norton, 10·1 in Stockton-on-Tees, 10·3 in Handsworth, 11·0 in Hornsey and in Bournemouth, and 11·1 in Leyton; the highest rates were 21·6 in Bolton, 22·1 in Liverpool, 22·7 in Bootle, 22·9 in Middlesbrough, 23·1 in Newcastle-on-Tyne, 23·3 in Salford, 24·6 in Birkenhead, and 26·1 in Rochdale. The 4894 deaths in these towns last week included 519 which were referred to the principal zymotic diseases, against 550, 534, and 489 in the three preceding weeks; of these 519 deaths 141 resulted from whooping cough, 112 from measles, 79 from diphtheria, 62 from small pox, 46 from scarlet fever, 42 from diarrhœa, and 37 from "fever" (principally enteric). In Ipswich, Norwich, Nottingham, Newport (Mon.), Swansea, and seven other smaller towns, no death from any of these principal zymotic diseases was registered; while they caused the highest proportional mortality in Tottenham, Hanley, Birmingham, Birkenhead, Oldham, Burnley, Barrow-in-Furness, and South Shields. Measles was proportionately most fatal in Bournemouth, Oldham, Burnley, Barrow-in-Furness, Huddersfield, West Hartlepool, and Gateshead; scarlet fever in Middlesbrough; diphtheria in Tottenham, Hanley, Coventry, and Merthyr Tydfil; whooping cough in Leyton, Plymouth, Birmingham, Birkenhead, Barrow-in-Furness, and South Shields; and "fever" in Birkenhead. Of the 62 fatal cases of small pox registered last week 44 belonged to London, eight to West Ham, four to Tottenham, two to East Ham, and one each to Willesden, Leyton, Walthamstow, and Burnley. The Metropolitan Asylums hospitals contained 1419 small pox patients on Saturday last, May 10th, against 1431, 1515, and 1442 on the three preceding Saturdays; 248 new cases were admitted during the week, again 328, 367, and 250 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 2155, 2188, and 2222 at the end of the three preceding weeks, had declined again to 2212 at the end of last week; 256 new cases were admitted during the week, against 269, 283, and 258 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 316, 315, and 240 in the three preceding weeks, further fell to 231 last week, and were 39 below the corrected average number. The causes of 57, or 1·2 per cent., of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Salford, Bradford, Leeds, Hull, and in 46 other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Liverpool, St. Helens, Rochdale, Blackburn, Sheffield, Sunderland, and Swansea.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24·6, 21·1, and 18·9 per 1000 in the three preceding weeks, further declined to 18·1 per 1000 during the week ending May 10th, but was 0·9 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 9·9 in Leith and 16·9 in Edinburgh to 20·3 in Perth and 21·1 in Paisley. The 586 deaths in these towns included 16 which were referred to whooping cough, 13 to diarrhœa, nine to measles, four to scarlet fever, three to diphtheria, and one to "fever." In all 46 deaths resulted from these principal zymotic diseases last week, against 63, 70, and 78 in the three preceding weeks. These 46 deaths were equal to an annual rate of 1·4 per 1000, which was 0·4 per 1000 below the zymotic death rate last week in the 76 large English towns. The fatal cases of whooping-cough, which had been 29 and 28 in the two preceding weeks, declined last week to 16, of which eight were registered in Glasgow, five in Aberdeen, and two in Edinburgh. The deaths from diarrhœa, which had increased from eight to 23 in the four preceding weeks, declined again to 13 last week, and included six in Glasgow, four in Edinburgh, and two in Aberdeen. The fatal cases of measles, which had been 13 and 15 in the two preceding weeks, declined again last week to nine, of which three occurred in Glasgow, two in Dundee, and two in Paisley. The deaths from scarlet fever, which had been five and two in the two preceding weeks, rose again to four last week, and included two in Glasgow, where the three fatal cases of diphtheria also were registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 199, 161, and 138 in the three preceding weeks, further declined last week to 113, and were slightly below the number in the corresponding period of last year. The causes of 20, or more than 3 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death rate in Dublin, which had been 28·8 and 24·9 per 1000 in the two preceding weeks, further declined to 22·6 per 1000 during the week ending May 10th. During the past four weeks the death-rate has averaged 24·3 per 1000, the rates during the same period being 17·0 in London and 18·5 in Edinburgh. The 164 deaths of persons belonging to Dublin registered during the week under notice were 17 below the number in the preceding week, and included 12 which were referred to the principal zymotic diseases, against 10 and nine in the two preceding weeks; of these, six resulted from measles, two from whooping-cough, two from "fever," and two from diarrhœa. These 12 deaths were equal to an annual rate of 1·7 per 1000, the zymotic death-rate during the same period being 2·3 in London and 1·3 in Edinburgh. The fatal cases of measles, which had been two, two, and three in the three preceding weeks, further increased last week to six. The deaths referred to different forms of "fever," which had been four and three in the two preceding weeks, declined to two last week. The mortality from both whooping cough and diarrhœa was in excess of that recorded in the preceding week. The 164 deaths in Dublin last week included 34 of children under one year of age and 39 of persons aged upwards of 60 years; the deaths of infants were 13 above, and those of elderly persons 13 below, the respective numbers recorded in the preceding week. Seven inquest cases and four deaths from violence were registered; and 64, or more than a third, of the deaths occurred in public institutions. The causes of 10, or more than 6 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING APRIL, 1902.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the cities and boroughs in the county of London. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 10·5 per 1000 of the population, estimated at 4,579,107 persons in the middle of the year. In the three preceding months the rates had been 11·4, 11·4, and 11·9 per 1000 respectively. The rates were considerably below the average in Hammersmith, Fulham, Chelsea, the City of Westminster, Hampstead, and Stoke Newington, while they showed the largest excess in St. Pancras, Hackney, Bethnal Green, Stepney, Poplar, and Southwark. The prevalence of small pox last month showed a considerable decline from that recorded in the preceding month; the greatest proportional prevalence of this disease was recorded in Hackney, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, and Woolwich. The Metropolitan Asylums hospitals contained 1442 small pox patients at the end of last month, against 1135, 1309, and 1526 at the end of the three preceding months; the weekly admissions averaged 319, against 390 and 461 in the two preceding months. The prevalence of scarlet fever during the month under notice was very slightly in excess of that recorded in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in St. Pancras, Southwark, Battersea, Wandsworth, Camberwell, Deptford, and Lewisham. The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals, which had been 2501, 2250, and 2113 at the end of the three preceding months, had risen again to 2176 at the end of last month; the weekly admissions averaged 253, against 266, 234, and 258 in the three preceding months. Diphtheria also, was slightly less prevalent during April than in the previous months of this year; the greatest proportional prevalence of this disease occurred in St. Pancras, Islington, Hackney, Poplar, Camberwell, and Lewisham. There were 1035 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 1231, 1164, and 1123 respectively at the end of the three preceding months; the weekly admissions averaged 140, against 167, 164, and 156 in the three preceding months. The prevalence of enteric fever showed no variation from that recorded in the preceding month; among the various metropolitan boroughs "fever" was proportionally most

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING APRIL, 1902.

liquid is treated with ether to remove fat and other extraneous bodies. Finally, the residual liquid is made alkaline with potassium carbonate or hydrate and treated with chloroform which dissolves the liberated alkaloid. The chloroform is separated and poured off and on allowing it to evaporate atropine in a fair state of purity will remain which can be tested both chemically and physiologically. This excerpt from an early number of THE LANCET is interesting in relation to the history of alkaloids.

THERE will be a general meeting of the Medico-Legal Society on Thursday next, April 10th, at 5.30 P.M., at 20, Hanover-square, London, for the purpose of adopting rules and appointing officers. All who are interested in the work of the society are invited to attend. Particulars may be obtained from the secretaries, Dr. McCallin or Mr. R. Henslowe Wellington, 20, Hanover-square, W.

IT has been decided to inaugurate a post-graduate course of clinical demonstrations at Westminster Hospital during the coming summer session. The demonstrations will be held on Tuesdays at 4.30 P.M., commencing on May 13th.

SOME ACCOUNT WITH ILLUSTRATIONS OF "CHRONIC GLAUCOMA."

BY ONE WHO HAS IT.

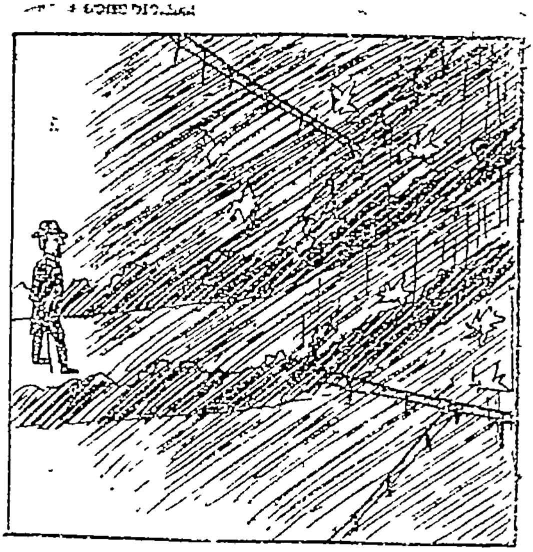
THE records of men who in the cause of humanity and medical science carry a fierce enthusiasm *usque ad mortem* are happily ever being brought up to date. The idea that a man should wilfully contract a disease in order that he may fully grasp its most minute symptoms and be more competent to relieve others who suffer from it is no longer considered a vain phantasy. There are, however, some diseases too malignant or exclusive to be assumed at will and among them must rank specific ocular diseases such as chronic glaucoma which seems to be also known under the title of "grey atrophy."

Pending the time when a medical expert shall contract this disease and lucidly and scientifically describe its most minute details a poor layman, whose only merit is that he suffers from it, gives here his personal knowledge of an undesirable malady in the hope that some reader may see here and there some further light to guide him in his work; and also with the idea that the strange vagaries of the eye alluded to may give some slight further inkling to the cause and seat of dreams, which vagaries may be likened to the probable productions of an automatic photo-camera out of gear.

Physical condition and appearance.—The patient's height is six feet and his weight has never exceeded 11 stones and two pounds. He is active in habits, is somewhat restless, and is nervous and slightly irritable. He has a wiry appearance and a very meagre flesh covering, is a great walker, and is able to get over 30 miles in a day without distress. An advertisement writer, his sight has for many years been taxed to its utmost, but the eyes had never given very serious trouble until about five or six years ago, when his work caused him to live in Manchester, which, on account of its ceaseless clatter and humidity, is a stronghold of nerve shatter and rheumatism. After about 18 months' residence there the patient was attacked by what was at first called muscular rheumatism but which eventually developed into general neuralgia, appearing at gradually lessening intervals. Two years ago the nasal nerves were specially affected, and as a result twice or three times a week there was a copious watery discharge from the eyes and nose. This usually came on at night suddenly and was preceded by a sharp stinging sensation in either nostril. This prevented sleep and in the daytime made work very difficult, necessarily causing considerable worry. Slight failure of the eye then occurred, of which, unfortunately, little notice was taken. Rather more than a year ago reading became difficult, the letters appearing to flow into one another, fancy-pointed type being most easily discernible. This appears to bear out what a writer in a recent issue of THE LANCET stated, as to a man suffering from partial blindness being better able to read Greek than any other language. On consulting Dr. O. E. Glascott he diagnosed the disease as chronic glaucoma, a hopeless complaint, always going from bad to worse and liable through influenza or a bad cold to end in darkness. No treatment was likely to be of any avail, and the only vestige of consolation lay in the fact that a kind of record had been established by the disease being contracted at the age of 40 years instead of at 60 years, as usual. The general outlook at this period presented the appearance of a continuous summer haze.

Rapid development of the disease.—In two months' time a slight mist had grown into a thick fog of a dark grey aspect. Further medical assistance was sought, Mr. E. L. Luckmann of Altrincham Eye Infirmary taking the case in hand and giving tonics to which iodide of potassium was added. This treatment had a decidedly beneficial effect and appeared at least to arrest the progress of the complaint and even at times to improve the vision. Unfortunately, however, owing to a very bad chill, caught when making a sea trip to Glasgow, the small hopes of amelioration were dispelled, and with the exception of a slight appreciation of the light a state nearly approaching to blindness ensued and the patient had to be led about. The following illustration represents the patient's view of part of the country through which he walked on his first visit to Altrincham. It looks as if the peaceful fields were being shelled by an enemy. The phenomena only occurred after much physical exertion and the bursts of light were accompanied by a very slight cracking noise. (Fig. 1.)

FIG. 1.



This shows the patient going along a country road, fields on either hand. The lighter spots locate the apparent position of the bursts of light referred to.

It should be mentioned that this ocular peculiarity occurred after considerable physical exertion only. This next sketch represents a very crowded Manchester thoroughfare on a clear day as it appears at the time of writing. Nothing is visible except an occasional dark shadow. The one shown in the sketch represents a man who has passed near enough to tread on the patient's toes. None of the road traffic can be seen at all. (Fig. 2.)

During the past few weeks, in addition to a chronic stickiness of the eyelids, a kind of paralysis of the nose, the lips, and the chin has set in, making speech occasionally quivering. There has also been periodical numbness of the forehead. It may be mentioned that when in Glasgow the patient attended the Ophthalmic Institute and was seen by Professor A. Maitland Ramsay who confirmed all that Dr. Glascott had said, calling the disease, however, by a different name—"grey atrophy."

Permanent optical illusion.—In the advanced state of the disease the only thing capable of being visually appreciated with anything like correctness was a large blot of ink on white paper held close to the eye. The patient finds it a great relief to keep the lids closed as much as possible, but prevalent in Hackney, Holborn, Shoreditch, Poplar, Southwark, and Deptford. The number of enteric fever patients in the Metropolitan Asylums hospitals, which had been 128, 142, and 121 at the end of the three preceding months, had further declined to 115 at the end of last month; the weekly admissions averaged 17, and corresponded with the number in the preceding month. Erysipelas was proportionally most prevalent in St. Marylebone, Bethnal Green, Poplar, Southwark, Deptford, and Greenwich. The 26 cases of puerperal fever notified during the month included three in St. Pancras, three in Islington, and two each in Paddington, Chelsea, Shoreditch, and Woolwich.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, *the deaths occurring in public institutions* having been distributed among the various boroughs in which the deceased persons had previously resided. During the five weeks ending May 3rd the deaths of 7374 persons belonging to London were registered, equal to an annual rate of 16·8 per 1000, against 18·3, 25·9, and 20·4 in the three preceding months. The lowest death-rates last month in the various metropolitan boroughs were 11·6 in Hampstead, 13·5 in Wandsworth, 13·6 in Lewisham, 13·9 in Kensington and in Stoke Newington, and 14·1 in the City of Westminster; the highest rates were 21·2 in Stepney and in Poplar, 21·3 in Southwark, 21·6 in the City of London, 22·2 in Bethnal Green, 22·3 in Finsbury, and 23·0 in Holborn. The 7374 deaths from all causes included 254 from small-pox, 294 from measles, 50 from scarlet fever, 112 from diphtheria, 225 from whooping-cough, 16 from enteric fever, and 60 from diarrhœa; in all, 1011 deaths were referred to these principal zymotic diseases, equal to an annual rate of 2·3 per 1000. The lowest death-rates last month from these diseases among the various boroughs were 0·6 in the City of Westminster, 0·8 in Stoke Newington, 1·1 in Hampstead, 1·2 in Paddington, 1·3 in Kensington, and 1·5 in Lambeth and in Wandsworth; the highest rates were 3·3 in Fulham, 3·4 in Holborn and in Shoreditch, 3·5 in Bermondsey, 3·8 in Bethnal Green, and 4·1 in Stepney. The 254 fatal cases of small-pox showed a slight decline from the numbers recorded in the two preceding months; the greatest proportional mortality from this disease occurred in Hackney, the City of London, Bethnal Green, Stepney, Poplar, Greenwich, and Woolwich. The 294 deaths from measles were 95 below the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Hammersmith, Fulham, Chelsea, St. Marylebone, Holborn, Finsbury, Bethnal Green, and Battersea. The 50 fatal cases of scarlet fever showed a decline of 20 from the corrected average number; the greatest proportional mortality from this disease was recorded in Chelsea, St. Marylebone, Hampstead, St. Pancras, Battersea, and Lewisham. The 112 deaths from diphtheria were 60 below the average number in the corresponding periods of the 10 preceding years. Among the various metropolitan boroughs this disease was proportionally most fatal in Hammersmith, Islington, Finsbury, Poplar, and Camberwell. The 225 fatal cases of whooping-cough showed a decline of 85 from the corrected average number; the greatest proportional mortality from this disease occurred in Holborn, Finsbury, Shoreditch, Bethnal Green, Stepney, and Bermondsey. The 16 deaths referred to enteric fever were also less than one-half of the corrected average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Hackney, Southwark, Lambeth, Camberwell, and Lewisham. The 60 fatal cases of diarrhœa also showed a slight decline from the corrected average number; the highest death-rates from this disease were recorded in St. Marylebone, Hampstead, Shoreditch, Southwark, Bermondsey, and Battersea. In conclusion, it may be stated that the aggregate mortality in London last month from the principal zymotic diseases was more than 2 per cent. below the average.

Infant mortality in London during April, measured by the proportion of deaths among children under one year of age to registered births, was equal to 128 per 1000. The lowest rates of infant mortality were recorded in Paddington, St. Marylebone, Hampstead, Stoke Newington, Greenwich, and Lewisham; and the highest rates in St. Pancras, Holborn, Shoreditch, Bethnal Green, Poplar, and Wandsworth.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: J. H. Lightfoot to the *Formidable* and A. R. Thomas to the *Hearty*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel T. M. Corker proceeds to Woolwich and Lieutenant T. Biggam joins at Hounslow for duty.

Lieutenant Howard Ensor, D.S.O., is seconded for service with the Egyptian Army. Dated May 2nd, 1902.

Major S. C. Philson, from the Seconded List, to be Major, vice R. E. Kelly, placed on half-pay. Dated April 16th, 1902.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant C. F. Spinks having resigned his Volunteer appointment, ceases to belong to the Army Medical Reserve of Officers. Dated May 10th, 1902.

IMPERIAL YEOMANRY.

36th Battalion: Richard Ahern to be Medical Officer, with the temporary rank of Captain.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers).—1st Newcastle-on-Tyne: Lieutenant George Nicol Wilson resigns his commission and is appointed Surgeon-Lieutenant. 1st Norfolk: William Oliver Beddard to be Surgeon-Lieutenant.

Rifle: 1st Volunteer Battalion the Royal Scots Fusiliers: *Brigade-Surgeon-Lieutenant-Colonel* W. Wilson *reverts to* the rank of Surgeon-Lieutenant-Colonel on relinquishing the appointment of Senior Medical Officer to the late Clyde Volunteer Infantry Brigade on reorganisation. 2nd (Earl of Chester's) Volunteer Battalion the Cheshire Regiment: Brigade-Surgeon-Lieutenant-Colonel H. W. King is seconded whilst holding the appointment of Senior Medical Officer to the Cheshire Volunteer Infantry Brigade. 1st (Ross Highland) Volunteer Battalion Seaforth Highlanders (Ross-shire Buffs, the Duke of Albany's): Surgeon-Lieutenant J. Cameron to be Surgeon-Captain. 3rd (Morayshire) Volunteer Battalion, Seaforth Highlanders (Ross-shire Buffs, the Duke of Albany's): Surgeon-Captain G. C. Milligan resigns his commission. 1st (Inverness-shire Highland) Volunteer Battalion the Queen's Own Cameron Highlanders: Lieutenant-Colonel Thomas Ranken Macdonald, late Indian Medical Service, to be Surgeon-Lieutenant-Colonel. 3rd (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): Charles Whish to be Surgeon-Lieutenant.

BEARER COMPANY.

Harwich: William Alexander Gibb to be Surgeon-Lieutenant.

SOUTH AFRICAN WAR NOTES.

Lieutenant Beatty, R.A.M.C., was reported "not so well" on May 10th, having previously been reported "improving."

Captain A. E. Smithson, R.A.M.C., and Civil Surgeon Burch are returning from South Africa to England in the s.s. *Canada*, which left Cape Town on May 7th.

THE VICTORIA CROSS.

The King has signified his intention to confer the decoration of the Victoria Cross on Surgeon-Captain A. Martin-Leake, South African Constabulary, for his conspicuous bravery in South Africa. "During the action at Vlakfontein on Feb. 8th, 1892, Surgeon-Captain Martin-Leake went up to a wounded man and attended to him under a heavy fire from about 40 Boers at 100 yards range. He then went to the assistance of a wounded officer, and whilst trying to place him in a comfortable position was shot three times, but would not give in till he rolled over thoroughly exhausted. All the eight men at this point were wounded, and while they were lying on the veldt Surgeon-Captain Martin-Leake refused water till every one else had been served."

"MENTIONED IN DESPATCHES."

This is the title of a useful publication which has just been issued by the *Army and Navy Gazette* (York-street, Covent-garden, W.C.) at the price of 1s. net. It contains in a handy form lists of all the officers and men of the Royal Navy and the Army who have been mentioned in despatches and have received honours and promotions for their services in South Africa from the beginning of the war in 1899 to May 6th, 1902. The lists have been compiled from official gazettes and have been thoroughly revised and corrected in accordance with later *London Gazettes*. Inasmuch as some of the issues of the *London Gazette* containing the South African war despatches are now out of print the book is of great value as a work of reference. Among the list of those who have gained the Victoria Cross are the names of Lieutenant-Colonel Babtie, C.M.G., R.A.M.C.; Surgeon-Captain Crean, Imperial Light Horse; Lieutenant Douglas, R.A.M.C.; Captain Howse, New South Wales Medical Staff Corps; Captain Inkson, R.A.M.C.; and Captain Nickerson, R.A.M.C (It will be seen from another paragraph on page 1425 that the name of Surgeon-Captain A. Martin-Leake, South African Constabulary, must now be added to this list.) One K.C.B was conferred upon a member of the medical profession for services in connexion with the war—namely, on the late Sir William MacCormac, Bart., K.C.V.O., and 20 C.B.'s, two K.C.M.G.'s, 47 C.M.G.'s, and 37 D.S.O.'s have been received by members of the medical profession. Non-commissioned officers and men of the Royal Army Medical Corps have had 38 Distinguished Conduct medals, and a sergeant-major a bar for the medal he already possessed.

Two D.S.O.'s have been conferred upon medical officers of the Royal Navy.

Upon nursing sisters and other ladies 48 Royal Red Crosses have been bestowed.

AUGMENTATION OF THE GERMAN NAVY.

It is well known that Germany intends to become a first-class naval power in the near future. This is clearly shown in the scheme for increasing the *personnel* of the navy which has been elaborated by the authorities. According to this document the strength of the German navy in 1920 will be as follows: executive officers, 2088; engineers, 427; paymasters, 234; and petty officers, bluejackets, stokers, and torpedo hands, 54,920. The strength of the medical department has been more than doubled, as shown below:—

Medical officers of the	Strength, 1900.	Strength, 1920.	Increase.
First class	1	1	—
Second ,, ...	2	4	2
Third ,, ..., ...	26	83	57
Fourth ,, ...	56	115	59
Fifth ,, ...	68	138	70
Totals	153	341	188

Of the above upwards of half are designated for sea service as follows: second-class medical officer, 1; third-class, 55; fourth-class, 61; fifth-class, 69; total, 186. One-fifteenth of the officers belonging to the last two classes are to be detached annually from general service for instruction in the various scientific institutions at Berlin. The number of medical officers of all grades for duty at the different stations has been established in the following manner: (1) Service afloat. North Sea Fleet (active list), 56. Ditto (reserve), 35. Vessels absent from home waters, 40. Ditto (for relief), 20 Training ships, 16. Special service ships, 5. (2) Service on land. Berlin, 22; Kiel, 70; Dantzig, 2; Friedrichson, 3; Wilhelmshaven, 66; Lehe, 2; Cuxhaven, 2; Heligoland, 1; Yokohama, 1; total, 341. The names of a few medical officers at Kiel and Wilhelmshaven are on the sea-going list.

THE ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES.

The eleventh annual meeting of this association will be held at Washington, D.C., on June 5th, 6th, and 7th, 1902, under the presidency of Lieutenant-Colonel John Van R. Hoff, Deputy-Surgeon-General of the United States Army. Some important papers dealing with medical military subjects will be read during the meeting and there will be an exhibition of medico-military materials Major James Evelyn Pilcher, Brigade-Surgeon, U.S.V., whose address is Carlisle, Pennsylvania, will act as secretary to the meeting.

ISOLATION ACCOMMODATION.—Dr. F. St. George Mivart, of the Local Government Board, conducted an inquiry on April 16th at Stroud in reference to the application of the local joint hospital board for permission to borrow £12,500 for the purpose of erecting an infectious diseases hospital upon a site already acquired at Carles Green, Stroud.

Correspondence.

"Audi alteram partem."

THE BATTLE OF THE CLUBS: THE COVENTRY PUBLIC MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—As this organisation has now been in existence for 10 years we are in a position to lay before the profession the result of our work in the interest of reform in medical contract work. As a result of this strong combination in the profession we may pride ourselves on the fact that Coventry has taken the foremost position in this pioneer work. Built upon the ashes of medical aid associations it may now be regarded as the largest existing organisation under professional control. The recent decision of the General Medical Council on the question of medical aid associations appears to render some agency of this kind a necessity to medical men. Each city or town should absorb in a service under its own control the bulk of these patients or those suitable for club or dispensary treatment. Many problems affecting the profession may under these conditions attain a certain measure of solution. In our experience there is no necessity to admit the lay element on the committee of management. Coöperative societies, trade unions, or other kindred combinations have attained an extraordinary measure of success under the management of working-men so-called. Why should not medical men possess the necessary business talent to develop a working scheme capable of protecting their own interests? Our service has now enrolled 10,000 members under a wage-limit and our gross receipts for the year amounted to £1986 17*s.* 6*d.* We paid to our chemists £456 4*s.* 2*d.* and the medical officers, after deducting all working expenses, were paid £1238 15*s.* 6*d.* We have some slight expense in organising our scientific branch, some of our work being thus carried on in the interest of medical progress. We have had during the year 10 meetings at which there were addresses and discussions of great value to the profession. Amongst those taking part were Dr. E. Malins, Dr. E. Rickards, Mr. G. Heaton, and Mr. J. F. Hall-Edwards of Birmingham, Dr. J. H. Sequeira, Dr. L. Hemington Pegler of London, and Mr. J. E. Swindlehurst, city engineer of Coventry. We thus combine together in our service the scientific and the commercial interests of the profession. During the year 2684 new members joined, mostly of the labouring class, and our collections over the previous year showed an increase of £150 19*s.* 8*d.*—I am, Sirs, yours faithfully,

W. RICHARDSON RICE, M.D., Honorary Secretary.

May 11th, 1902.

INHALATION.

To the Editors of THE LANCET.

SIRS,—In the Baillie lecture delivered by Dr. W. H. Dickinson at St. George's Hospital and published in THE LANCET of May 10th, p. 1297, there are some remarks on inhalation which deserve attention. They are as follows: "Whether we shall ever find a way of killing the visitor without doing serious damage to the host is a question for the future—we have not done so yet." May I observe on this remark that we are not likely to do so while such opinions prevail. In an old number of St. George's Hospital Reports a short paper was published on Some Remarks on Inhalation. There was a quotation in it from Dr. Paris on inhalation to this effect: "Unfortunately the injudicious and empirical spirit with which these inquiries have hitherto been conducted has thrown such discredit upon the subject that the practitioner who would resume the investigation must be prepared to hear his understanding or his integrity questioned."

In THE LANCET of May 21st, 1892 (p. 1130), just 10 years ago almost to a day, you were good enough to publish a paper on the Scientific Principles of Inhalation. It was written with the intention of relieving the subject of inhalation to some extent from the "discredit" that Dr. Paris remarked upon. How the vapores of our old Pharmacopœia with their totally inefficacious directions for administration could be tolerated by the profession was a mystery to me only to be accounted for by complete ignorance of the subject, and I think one of the most laudable changes made was their extermination. We all should take an active interest in the subject of inhalation, and it seems wiser and better to try to improve than to sit still and wait for a future that patience will not help

I am, Sirs, yours faithfully,
May 13th, 1902. ROBERT J. LEE.

DOES PUERPERAL ECLAMPSIA TEND TO RECUR?

To the Editors of THE LANCET

SIRS,—A question of considerable medical interest has arisen in the course of my practice. A patient of mine had during her first confinement a most serious attack of puerperal eclampsia from which, after long and anxious watching, she recovered. Her husband, who is naturally anxious, has now appealed to me as to the risk she would run of again incurring this formidable complaint in the event of her becoming pregnant a second time. Not wishing to take the responsibility of answering this grave question on my own limited experience I at once consulted all the leading authorities, from the time of Churchill up to the present day, on the subject, without gaining the slightest assistance in my dilemma. Such being most unsatisfactory, I at once bethought me of your valuable journal and decided to write you in the hope that some among your readers and contributors might have it in their power to help me in this most awkward predicament. Thanking you in anticipation,

I remain, Sirs, yours faithfully,
D. F. MACGILLICUDDY, M.B., B.S. Melb.
Richmond, Victoria, Australia, March 24th, 1902.

LARGE DOSES OF STRYCHNINE IN SURGICAL SHOCK.

To the Editors of THE LANCET.

SIRS,—If Mr. C. Hamilton Whiteford thinks that I have failed to appreciate the difference between strychnine in one large dose administered to a non-collapsed patient and graduated doses of the same drug given to a patient suffering from shock I may at once disabuse his mind of the fallacy which he labours under. My strictures referred to the ideal system so ably championed by Mr. Whiteford, and the questions which I asked the advocates of this new form of drugging were framed, not in the study, but were prompted by bedside observation. If my theory of the terrific spasms is perfect, as Mr. Whiteford says it is, I am glad to hear it, for, unlike many theories, it was made to fit facts observed. If I might be allowed an opinion in the matter I should say it is fact without any theory. Now for the case.

A man, 70 years of age, suffered from intestinal obstruction and had colotomy performed under ether. The operation itself was perfect. Before operation he was given one-tenth of a grain of strychnine hypodermically and soon after the operation was completed another one tenth of a grain was administered in the same manner. Later at intervals he had one-twentieth of a grain on three separate occasions as was considered necessary to make the pulse "buck up." From first to last he had seven-twentieths of a grain of strychnine hydrochloride, or equal to 35 minims of the pharmacopœial solution. When the effects of the ether had quite passed off then little by little began the train of symptoms which I enumerated in my last letter. First there was twitching, then great irritability of the reflexes, next clonic and tonic spasms of the vital reflexes, till when toxicity was fully developed the nurse told me, without any prompting, that she was afraid to walk across the room for fear of starting the spasm of the respiratory muscles. For hours before the patient died it was impossible to get him to swallow anything, the least attempt in that direction being enough to induce a series of clonic spasms followed by a long tonic spasm, and I had to give large doses of chloral by the rectum to combat the strychnine action.

Potent drugs can be given in much larger amount than the authorised dose, but if we go right up to the maximum of safety, as is now being done with strychnine, here and there disasters will occur. I write in no mood of carping criticism, for with every honest endeavour to fight death I am in hearty accord, but where I believe the bounds of safety have been transgressed I feel it my duty to protest, and I think that my experience as given above justifies the stand I now take.

I am, Sirs, yours faithfully,
Leeds, May 10th, 1902. GORDON SHARP.

To the Editors of THE LANCET.

SIRS,—As house surgeon in a large provincial hospital where a great number of severe operations are performed I have had many opportunities of watching the after-effects of large doses of strychnine administered on the operating table. Varying amounts from 10 to 60 minims are frequently injected hypodermically when the patient has much shock. In most cases no ill effects are to be detected but in a considerable number I have noticed involuntary painful muscular spasms a few hours afterwards which have been relieved by the hypodermic injection of morphia. The largest dose given without any after symptoms was 30 minims during an operation for perforated gastric ulcer, the patient recovering. The largest dose given that produced slight spasms was 60 minims, also in a case of gastric perforation. The patient died five days later. The smallest dose given with spasms following was 26 minims to a girl 16 years of age with general peritonitis from a sloughing appendix who died the day following the operation. I am inclined to think that toxic symptoms are more likely to follow when ether has been the anæsthetic than when chloroform has been given.

I am, Sirs, yours faithfully,
F. BOLTON CARTER, F.R.C.S. Eng.
The Infirmary, Leicester, May 12th, 1902.

To the Editors of THE LANCET.

SIRS,—I should like to add my testimony to that of Dr. J. Gordon Sharp that in an operative case where strychnine had been injected hypodermically the tonic and clonic spasms of the muscles of the extremities remained after the effects of the anæsthetic had passed off, and, indeed, until the death of the patient nearly a week after, and caused a great deal of suffering. I am, Sirs, yours faithfully,
Leeds. JOHN J. PICKLES, M.R.C.S. Eng., &c.

THE GERMAN CONGRESS OF INTERNAL MEDICINE.

(FROM OUR BERLIN CORRESPONDENT.)

THE twentieth German Congress of Internal Medicine met this year at Wiesbaden, Professor NAUNYN of Strassburg being in the chair. The members on their arrival were, as usual, welcomed by the local authorities and by representatives of the medical profession. Professor von Leyden, the founder of the Congress, whose seventieth birthday has just been celebrated in Berlin with much enthusiasm, was then elected an honorary member of the Congress and the chairman took the opportunity of paying a tribute to his great merits as a clinical observer, a man of science, and a practical physician. In his reply Professor VON LEYDEN said that he, together with several other physicians, founded the Congress because it seemed as if internal medicine was falling behind other branches of medicine, especially in view of the surprising progress made by surgery and gynæcology. The Congress of Internal Medicine, the Berlin Society of Internal Medicine, and the *Journal of Internal Medicine* were intended to uphold and to maintain the position of this department of medical science. It was then announced by the mayor of Wiesbaden that the municipal authorities had conferred the freedom of the city upon Professor von Leyden, who was thereupon formally presented with the document certifying his election.

Gastric Ulcer.

Professor EWALD (Berlin) said that gastric ulcer was more frequent in women than in men and was usually met with in persons between 20 and 30 years of age. Cancer originating in a gastric ulcer has been known to occur in a youth, 16 years of age, but such cases were rare. In gastric ulcer some authorities objected to the employment of tubes for the purpose of obtaining samples of ingested food in order that they might be submitted to examination, but tubes might be employed if hæmorrhage had not occurred recently. As to the amount of hydrochloric acid, Professor Ewald said that it might be either normal or increased or diminished and an excess of hydrochloric acid was therefore by no means characteristic of gastric ulcer, whilst lactic acid was often absent. It followed from this that the chemical examination of the contents of the stomach did not contribute much to the diagnosis of the disease. Hæmatemesis occurred in 54 per cent. of the cases; this symptom was, however, present in other diseases also, such as uræmia, cirrhosis of the liver, septic diseases, and in so-called vicarious menstruation. It was not possible to localise an ulcer of the stomach although the pylorus was known to be affected in the majority of cases. Speaking of the complications of gastric ulcer he said that hour-glass contraction of the stomach might be ascertained by direct inspection with the gastroscope, but no satisfactory form of this instrument had yet been made. Perforation of the ulcer into the abdominal cavity was attended by symptoms so characteristic that the diagnosis was very easy, but perigastric adhesions were difficult to recognise. In a good many cases the diagnosis was uncertain. Patients suffering from chlorosis, the early stage of tuberculosis, gall-stones, cancer of the gall-bladder, and gastric troubles connected with tabes were often supposed to be the subjects of gastric ulcer.

Professor **FLEINER** (Heidelberg) gave some account of what had been done by early observers of gastric ulcer, stating that it was known to Hippocrates whose dietetic prescriptions were judicious. He further mentioned the researches of Cruveilhier, Trousseau, Brinton, Leube, and Kussmaul. Treatment, he said, aimed at obtaining cicatrisation of the ulcer, and this might be accomplished by means of rest, adequate food, and appropriate medicines, especially salts of bismuth. The patient should eat as little as possible and in the beginning of the treatment should have only ice to suck, whilst milk was to be given by the rectum. No other food than milk should be allowed for four weeks; meat and vegetables might then be given, but fruits, acids, meat extracts, and other gastric irritants were to be prohibited. For convalescents a visit to the country was preferable to a course of treatment at a mineral spa. Relapses sometimes happened, especially when the patient had not been confined to bed for a sufficient time. In these cases irrigation of the stomach with a solution containing bismuth was the best treatment, for the bismuth often adhered to the floor of the ulcer and had been found there after the lapse of several days. The compound of bismuth protected the ulcer against irritation; it was also a disinfecting agent and promoted healthy granulation. Professor Fleiner had treated 500 cases of gastric ulcer without any death. Surgical aid was advisable, especially in stricture of the pylorus, and should be resorted to at an early period before cachexia developed Gastro enterostomy was the operation which gave the best results. In profuse hæmorrhage operations were, as a rule, useless.

In the discussion Professor **LEO** (Bonn) said that he was opposed to the use of tubes because they irritated the ulcer.

Dr. **PARISER** (Homburg) drew attention to erosions of the stomach, a condition which ought to be distinguished from gastric ulcer proper.

Professor **SAHLI** (Berne) expressed the opinion that in gastric ulcer operative interference should be avoided as much as possible, for the great majority of these ulcers healed under internal treatment

Dr. **ADOLPH SCHMIDT** (Bonn) discussed the genesis of gastric ulcers. He had discovered by experiments on animals that in lesions of the mucosa the contractility of the muscular coat was increased so that the edges of the wound were brought together, but in chlorosis the contractility of the muscular coat was diminished so that the lesion was left open and was liable to be attacked by the gastric juice.

Dr. **HIRSCHFELD** (Berlin) said that the development of cancer in a cicatrised gastric ulcer was less frequent than was generally believed.

The Parasites of Cancer.

Professor **VON LEYDEN** (Berlin) said that the increase of cancer in Germany and England had induced a great many observers to study its etiology. He then discussed the various themes of Cohnheim, Hausemann, and Ribbert. Cancer from an anatomical point of view consisted in a proliferation of epithelial cells together with a destruction of all the other cells. The exciting cause of this proliferation had not yet been discovered. Various parasites had been credited with possessing this power, but none of these hypotheses had stood the test of further investigation, so that any new discovery in that direction was received with some distrust. Very likely the parasites of cancer lived within the cells. Ribbert had asserted that a parasite living in a cell would destroy it but would not produce proliferation. Thi view, however, could be disproved by botanical analogies. There was sometimes in cabbage a growth very similar t cancer and known as "kohlhernie," in which plasmodia had been discovered by Dr. Woronin, a Russian *savant*. Thes plasmodia grew within the cells and produced first proliferation and then a destruction of them. The anæmia and the alterations of the urine which occurred in cance must be taken as symptoms of a general infection. Moreover, cancer had been communicated experimentally from one animal to another, of course of the same species. Professo von Leyden also mentioned a case where by accident student had drunk a fluid consisting of the gastric juice of patient suffering from cancer of the stomach, the resul being his death from cancer within two years. He the described plasmodia which were found within the proliferated cells in cancer, especially in fresh specimens, and wer very like those discovered by Dr. Woronin; the plasma o the cells appeared as if destroyed by the parasites. Professo von Leyden recently discovered masses of these corpuscle in capsules which were supposed to be sporangia. Simila masses had also been met with in a case of cancer of th lungs.

(*To be continued.*)

THE NICE HOSPITALS AND THE VICTORIA MEMORIAL.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

A Proposed Cottage Hospital for English-speaking Patien at Nice.—The Difficulty of Dealing with Infectious Ca in Hotels.—The War Department and the Municipa Hospital.

THE prevalence of small-pox on the Riviera has greatl stimulated the efforts of all who had already endeavoured t improve the hospital accommodation. At Nice especial there has been quite an agitation among the American an British visitors and residents in favour of building a cottag hospital. Some time ago the newly appointed British Consu at Nice, Mr. Alec McMillan, proposed that a memori should be established at Nice in honour of the late Quee Victoria. Of course there was a clergyman who suggested tha the memorial should take the form of a stained-glass windo for the beautification of his church. The British resident and their American friends displayed, however, a mor practical turn of mind. They warmly supported the propos of Dr. A. W. Gilchrist who argued that a cottage hospit would be of far greater service than a stained-glass windo particularly as there is no hospital with modern requisites i the town. A public meeting of American and Britis residents and visitors was held on March 16th last. In t course of a lengthy and interesting speech delivered on th occasion Dr. Gilchrist related the pathetic case of an Englis lady who was seized with a serious illness last year. S had been refused admittance to the Asile Evangéliq and was removed to the Hôpital de la Croix. "Y know," said Dr. Gilchrist, "the pitiful circumstances her death In the middle of the night, amidst the gloo and desolation which befit the antiquated institution th gave her refuge, she drew her last breath, not only depriv of those subtle influences which can rob even death of som of its terrors, but without the possibility of expressing h last wishes to anyone of her own tongue." Then anoth case was described of a lady who was eligible for admissio into the Asile Evangélique, but this patient required the ca of an experienced surgeon not available at the Asile, whe the insanitary surroundings and restricted space render unwise to attempt major surgical operations. Her end w hastened because there was no suitable hospital where s would have received the constant attendance and skill nursing which she needed. In many such cases Englis speaking medical men and trained nurses are absolute necessary. Another instance given was that of a young la of French parents but born and bred in England. Thou endowed with an exceptionally fine physique she had undergo an operation rendered necessary through insufficie care during childbirth. There was nothing particularly seri or dangerous about this case; but being a Roman Catho she could not enter the Asile Evangélique, and theref she went to the General Hospital, where she died fro blood-poisoning. There are many other such accidents on record, and the French as well as the practitioners have often complained about the unsuitable and insanitary conditions of the General Hospital.

The Asile Evangélique is more suited for a convalescent home. There are no proper provisions for serious surgical operations, no lying-in ward, no isolation pavilion for infectious cases, and it is only available for Protestants and members of the Orthodox Greek Church; Roman Catholics and Jews are not admitted. It therefore in no wise meets the most urgent requirements. What is wanted is a cottage hospital, or rather several cottage hospitals, where English-speaking patients, without any distinction of creed, can be treated under the best and most modern sanitary conditions by English-speaking medical attendants and fully-trained nurses. There should be a well-equipped operating-room, a surgical ward, a medical ward, a lying-in ward, and an isolated pavilion for infectious cases. Some of the beds, and these would constitute the Victoria Memorial, should be gratuitous; the others should be for paying patients attended by their own physicians. Of the latter there would be a considerable number, for in any serious case of illness it is obvious that many persons would prefer such a hospital to remaining in an hotel. They would also have a better chance of recovery. In regard to infectious diseases the need of such an institution is still more obvious, for there can be no doubt that the infectious fever cases and small-pox should not be treated at an hotel. The hotel-keepers are in considerable perplexity when such cases occur. If they compel the patient to leave they may be accused of inhumanity and may become unpopular among their customers. If they keep the patient the customers may take fright and leave the hotel. Under these circumstances many hotel keepers are willing to subscribe to the proposed cottage hospital. Cases have occurred where well-to-do patients have died in an outhouse, a shanty, or an abandoned workshop because there was no room to isolate them in their hotel. Of the six cases of small-pox which occurred this season among the British and American visitors one of the patients lived in a large tenement house. He was nursed by his brother and sister who were to be seen daily riding in the trams. Other tenants dwelling in the same house wanted to get away but having hired apartments for the season could not do so. It may be said that this patient could have been removed to the hospital of La Croix where infectious cases are taken in and where private rooms can be hired. But it is an antiquated institution devoid of modern requirements and there are only untrained Italian sisters who sometimes render themselves objectionable to Protestants.

Considering that the welfare of Nice depends largely on its foreign visitors and that the fear of small-pox has kept many of them away during the recent winter season the question naturally arises why the municipality has not taken active steps to provide proper accommodation, at least for the isolation of cases of infectious fever or small-pox. The better to answer this obvious question I called on the Mayor of Nice. The present Mayor, M Sauvan, has not been very long in office, but from gossip in medical circles I had already ascertained that he had manifested more than usual interest in all matters relating to the public health, and hopes are entertained that under his administration more rapid progress will be achieved. In any case M. Sauvan received me most courteously and was ready to supply the information I made bold to demand. He insisted that the grievance in regard to the condition of the hospitals had been a subject of anxiety to the municipality for a long time and many efforts at reform had been made. Unfortunately until recently the municipality was not master of the situation. It had a partner, and a very obstructive partner, in the person of the Minister of War. This is a difficulty which certainly would never occur to the mind of a British or American visitor when tempted to criticise the municipal deficiencies of Nice. We cannot conceive a British or American municipality being debarred from providing proper hospital accommodation by the action of the War Office, and this, too, in the piping times of peace. But the fact is that the General Hospital of Nice is a military as well as a civil hospital. Now the War Department is not in the least concerned about the welfare of Nice as a fashionable winter resort. The military authorities were satisfied with the hospital as it stood and were not going to trouble themselves about alterations. Negotiations were opened by the municipality with the War Office, plans were proposed and schemes devised, but the military authorities invariably put spokes in the wheels whenever the civil authorities tried to move in the matter and this caused endless delay. A solution of the difficulty has, however, at last been found. A contract has been signed by which the municipality takes over the entire management of the hospital. It will be able to select a new site and to build a new hospital without having to consult and to obtain the approbation of the War Office. On the other hand, the municipality undertakes to receive in its hospital all soldiers who are ill in exchange for a fixed payment per head per day from the War Office. Already it has been decided to abandon the present hospital and to build according to modern principles and on the pavilion system a large hospital some four or five miles away from the centre of the town. There will be no financial difficulty in the accomplishment of this much-needed reform. Nice is the most prosperous of the large towns of France. Its population now numbers 127,000 inhabitants and has increased to the extent of 20,000 during the last five years. The mayor thinks that the new hospital will take some two or three years to build and therefore he insisted that the solution of the difficulty which I had exposed was now in sight. In regard to infectious cases there will, of course, be one or more pavilions separated from the rest of the hospital and reserved exclusively for isolation purposes. In response to this explanation I ventured to suggest that as the land had not yet been bought it would be preferable to secure two different sites well apart from each other. There was no advantage—there might be some danger—in having both hospitals in the same grounds; they could not be kept too far apart. The mayor graciously promised that good note would be taken of this observation.

Of course, it is still too soon to say how far the building of this new municipal hospital will lessen the need of a cottage hospital for English-speaking patients. For the latter purpose £1500 have been collected. Hopes are entertained that £10,000 will be obtained and it is proposed to make a start as soon as £4000 are in hand. If these hopes are confirmed something may be done long before the new municipal hospital will be built. Also the new general hospital, however perfect it may be, will not meet the requirements of the British and American residents who want the attendance of fully trained English nurses and English-speaking medical practitioners. There might, however, be some arrangement made for an English ward at the general hospital and this might cost less than a separate hospital for English speaking patients.

In the meantime, and whatever may be the value of these suggestions, it is most urgently necessary that better means for treating and isolating cases of small-pox and infectious fevers should be provided. Even if such accommodation be of but a provisional character, it should be forthcoming before the opening of the next winter season.

Nice, April

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Opening of the New Hartley Botanical Laboratories at University College.

THE magnificently-equipped botanical laboratories presented to University College, Liverpool, by Mr. W. P. Hartley were opened on May 10th, when Mr. Hartley formally presented the buildings to the college authorities. In place of the customary ceremonial opening there was a presentation to Mr. Hartley of a gold key, and a similar memento was presented to Sir William Thiselton-Dyer, K.C.M.G., the director of Kew Gardens, in recognition of the address on the Study of Botany with which he favoured the large audience who assembled in the arts theatre of the college to witness the proceedings. The gathering was presided over by Mr. E. K. Muspratt and included Professor Marshall Ward (Cambridge University), Professor B. Farmer (Royal College of Science), Professor Weiss (Owens College, Manchester), Professor Potter (Durham University), Professor Bottomley and Professor Millar Thomson (King's College), Professor Smith (Yorkshire College), Sir John T Brunner, Principal Dale (University College, Liverpool), and a number of the college staff. Mr Hartley, on making the presentation, said that his object in providing the laboratories was to help in the discovery of truth and in the encouragement of science in its pure as well as in its applied branches—knowledge which not simply made their wealth more and their comfort greater, but which improved the mind and developed higher faculties and functions. Sir William Thiselton-Dyer, prefacing his address on botany, said that his feeling in coming to Liverpool from London was one of envy. He found a great commercial city full of busy life, possessing buildings and equipments for the pursuit of knowledge marked by a sumptuousness and magnificence the like of which was not possessed by them in London and there was no early probability of their possessing them. As had been indicated, the new laboratories were not intended to teach that which would lead to any direct profit or which would be utilitarian in effect. Botany was calculated to foster the faculties of carefulness and observation in the highest stage; the direct appeal to nature went down to the very simplest needs of ourselves. Bluntness of observation was a terrible thing, for the inability to see a thing at the moment it was there might mean the loss of a great and unique opportunity. The great Darwinian theory, one of the most startling ever sprung upon the the scientific world, sprang from Darwin's observation of the difference between the plants on two neighbouring small islands. The cultivation of the powers of observation was a valuable occupation, and botanists who had been trained in that way would always find the seeing eye of use. Sir William Thiselton-Dyer spoke of the great industries which had their origin in botanical discoveries and also of the value of the science to medicine, concluding with the remark that after the first 36 hours of our existence we were dependent on plant life until our death, and then it facilitated our decay. Professor Harvey Gibson, the lecturer in botany at University College, Liverpool, in seconding the vote of thanks which was proposed by Sir John Brunner, described the new laboratories as some of the greatest in the kingdom. They were designed to unite in the study of botany the scientific and commercial and economical aspects. Great problems were connected with the production of rubber, the preservation of fruits, and the treating of grain, and why should not these be solved in the Hartley laboratories?

May 13th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Physicians of Edinburgh.

A QUARTERLY meeting of the Royal College of Physicians of Edinburgh was held on May 6th, Dr. T. R. Fraser, the President, being in the chair. Mr. Dugald Christie of Moukden, Manchuria, was admitted by ballot to the Fellowship of the College. On a ballot Dr. Charles Mowbray Pearson was admitted to the Membership of the College after examination. The Registrar reported that since the last quarterly meeting 50 candidates had obtained the Licence of the College by examination. The Hill-Pattison Bursary, which is in the gift of the College, was awarded after a competitive examination in anatomy and physiology to Mr. James Grieve Cormac. Dr. William Fordyce was recognised as a Lecturer in Midwifery and Dr. Charles J. Lewis as a Lecturer in Public Health. Sir John Batty Tuke was unanimously re-elected Representative of the College on the General Medical Council for a period of five years from May 4th. The Secretary announced the re-election by the Council of Sir John Sibbald as Representative on the Conjoint Committee of Management of the Triple Qualification. On a motion by the Secretary it was resolved—

> That Law 2 of Chapter VI. be altered so as to read as follows: "The fee to be paid by a Member shall be 35 guineas."
>
> That Law 3 of Chapter VI. be altered so as to read as follows: "When a Licentiate shall be raised to the rank of Member he shall pay 25 guineas."
>
> That Law 4 of Chapter VI. be altered so as to read as follows: "When a Member shall be raised to the rank of Fellow he shall pay 38 guineas, exclusive of Stamp Duty."

Prevention of Spitting in Edinburgh.

At a meeting of the Edinburgh Public Health Committee on May 6th the committee agreed to recommend to the town council that 250 metal plates bearing notices asking the citizens not to spit on the pavement should be affixed to the electric lamp-posts throughout the city.

Edinburgh New Fever Hospital.

The Public Health Committee of the Edinburgh Town Council has recently approved of plans and provisional estimates submitted by the head city gardener and the city road surveyor for laying out the grounds and forming roads in connexion with the new fever hospital at Colinton Mains. The grounds are to be laid out so as to provide sufficient recreation space together with efficient isolation for each pavilion and at the same time to enhance the appearance of the group of buildings as seen from a distance. The cost is estimated at £4750, while the roads will cost an additional £4800. The Public Health Committee agreed to recommend to the town council that the roads should be proceeded with at once.

The Investigation of Cancer.

Mr. J. K. Caird, who three years ago provided, at a cost of over £8000, the Dundee Royal Infirmary with the wards and nurses' home in connexion with its gynæcological and maternity departments, last week offered to build an addition to the hospital to be devoted specially to the treatment of patients suffering from cancer, and also to defray the expense of a five years' research in the subject. The proposed building is intentionally very large, as it is Mr. Caird's desire that part should be used for general purposes if the whole is not required for cancer cases. The number of beds shown on the plans is 114 and the estimated cost is £18,500. The sum to be given for research purposes is £5000.

May 13th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Notification of Infectious Diseases in County Dublin.

IT is now more than a month since the Commissioners Blackrock adopted the provisions of the Notification of Infectious Diseases Act, and now, with the exception of Kingstown, every local body between Dublin and Waterford has followed the same course. At the last meeting of the Dublin Sanitary Association held on May 8th the following motion was unanimously adopted:—

> That the council of the Dublin Sanitary Association observe with disappointment and dismay that the Urban District Council of Kingstown has postponed the question of the adoption of the Infectious Diseases (Notification) Act, 1899, for the long period of 12 months. The council consider that in taking so grave a step the urban district council has lost sight of the interests of the important health resort intrusted to its care and has incurred a serious responsibility. Should epidemic disease break out in Kingstown it will probably spread far and wide before its presence is brought under public notice, tourist traffic will be interfered with, while Dublin and the other adjoining districts, which have now, without exception, adopted the Act will be endangered. The council trust that an effort will yet be made to rescind so unfortunate a decision at the earliest opportunity and that Kingstown will fall into line with the neighbouring districts.

The Royal City of Dublin Hospital.

The "Gigas" bazaar and fête in connexion with the Royal City of Dublin Hospital was opened on May 13th by His Excellency the Lord Lieutenant of Ireland and the Countess Cadogan. They were received by the Earl of Pembroke as representing the committee. The Lord Mayor of Dublin was present and proposed a vote of thanks to His Excellency, who in his reply spoke of the pleasure he felt in meeting the Lord Mayor on a platform where all could unite in the caus of charity.

Royal University of Ireland.

A meeting of Convocation of the Royal University o Ireland was held in Dublin on May 9th to elect six member to represent Convocation on the Senate, and such was th interest taken in the contest that 573 voting papers wer handed in. There were nine candidates and the followin six were elected:—His Honour Judge Shaw, LL.D., 39 votes; Mr. A. Anderson, M.A., President of Queen's College Galway, 366 votes; Mr. J. Walton Browne, M.D., 360 votes Professor T. Sinclair, M.D., 360 votes; the Rev. Professo Leitch, D.Lit., 334 votes; and Mr. E. Cuming, M.A., K.C. 322 votes. The issue upon which this election was fought wa the question of the employment of extern examiners in th University. The six senators elected were in favour of exter examiners in the various faculties of the University, bu especially in the faculty of medicine, and the Royal University Graduates' Association supported and recommende their candidature. The highest on the poll of the rejecte candidates, Sir W. Thomson, C.B., has long been an activ member not only of the Senate of the Royal University, bu also of its Standing Committee. In his election address h defined an extern examiner as one not officially connecte with any of the three Queen's Colleges (Cork, Galway, and Belfast) or with the Catholic School of Medicine, and no doubt he had the authority of a resolution of the Senat in support of this view. But, as was pointed out in the press by the secretary of the Graduates' Association, such a definition would not prevent persons engaged in teaching students of the Royal University in the Dublin hospitals from applying for examinerships, or hinder them if they got such posts from examining their pupils on the subjects that they had taught them. This state of things would not meet the requirements of the Graduates' Association, the members of which believed that in the interests of justice and of fairplay to provincial students the extern examiner, properly so called, should not "be connected in any capacity with any school, college, or university in Ireland." Sir W. Thomson regarded such a demand as a betrayal of Irish interests and an insult to Irishmen, and he protested in his address "against the implication that in order to obtain competent, honest, and impartial examiners we must go to England or Scotland and thus offensively exclude our own countrymen." This was an admirable card to play in an election address, but it failed, and the graduates have by their course of action in this election shown that what is wanted is not a multiplication of examiners but an addition of extern examiners not "connected with any school, college, or university in Ireland." The Royal University Graduates' Association is simply following the precedent set by other universities.

The Weather in the North of Ireland.

There has not been for many years such severe weather as that which has prevailed in the North of Ireland during the present month, which has been cold with a keen, withering north wind accompanied with hail.

Precautions against Accidental Poisoning in Hospitals

IT will be remembered[1] that last year a deplorable accident occurred at the Hôpital Lariboisière owing to the mistake of a nurse who gave several patients a poisonous substance in place of what had been ordered for them. With a view to guard against the recurrence of such dangers M Mourier, director of the Assistance Publique, has decided that henceforth all poisonous substances employed in the hospitals shall be kept in special receptacles impossible to be mistaken for the ordinary receptacles containing non-poisonous substances. The new receptacles are going to be tried at the hospital where the accident occurred. For amounts of from 15 grammes to one litre (from half an ounce to 35 ounces) the receptacles are glass bottles and for amounts of more than one litre they are earthenware jars Both the bottles and the jars are triangular, a shape which can be distinguished at the first glance from the ordinary cylindrical form. The triangular bottles will be made of yellow glass roughened on two surfaces in a manner perceptible to the touch, so that by their shape, *their colour*, and their roughness the bottles will appeal alike to the sense of sight and the sense of touch and mistakes will be absolutely impossible either in the light or in darkness. When the success of the new system is proved it can be extended to other hospitals and adopted generally.

Examinations in Medicine and Pharmacy.

Until recently, when a candidate had failed to pass an examination in medicine or pharmacy he had the right of again presenting himself in three months, and in the event of a second failure again in three months, and so on continually This system was, however, altered by a decree promulgated on July 24th, 1899. From that date, if a young man failed to pass the first time that he presented himself he had the right of presenting himself again in three months, but in the event of a second failure he would have to wait not for three months but for six months before again coming forward, and in the event of a third failure he would have to wait for 12 months This is evidently a serious hindrance to the completion of medical studies, for with this prospect of possible failures it becomes difficult to foresee at what date a student might hope to be able to finish his curriculum. Students have therefore commenced an agitation which they are actively carrying on in defence of their interests, and at the end of last February they protested in large numbers against the application of this decree, which could only have for its object the elimination of idle or incompetent students.

Motor Ambulance Vehicles.

Complaints have several times been made with respect to the slowness of the ambulance vehicles belonging to the city, for they are drawn by only one horse which is not always a very fast goer. The question of the speedy arrival of the vehicle at the scene of an accident being of the first importance it would at least be desirable for it to have two horses. Another thing is that the harnessing of the horses takes time. It would be very much quicker and more practical to use motor vehicles now that they are sufficiently speedy and trustworthy. For the daily removals of military patients special tramcars are used but even these are far from being perfect. The idea of letting them run on the tramway lines is an excellent one, for it makes the journeys both easier and quicker, but it is a mistake to use old vehicles and it would be a good thing if the military tramcars which are no longer serviceable were sent back to the car-builders, for those which are at present running in Paris have a deplorable appearance and this service is in several respects open to improvements.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Proposed Increase of the Medical Corps of the United States Navy.

SURGEON-GENERAL RIXEY, the head of the Medical Service of the United States Navy, who has recently been appointed to that position, has recommended, as one of his first official acts, that the medical corps of the navy should be increased by 40 medical officers, this increase to be made by the addition of 15 surgeons and 25 assistant surgeons. Owing to the increase in the size of the navy, the larger number of ships in commission, and the great amount of time lost by medical officers in changing station between the United States and the Philippines and other outlying stations, Surgeon-General Rixey finds considerable difficulty in furnishing proper medical attendance to the ships. He is of opinion that the addition should affect the higher as well as the lower grades, and points out that the senior passed assistant surgeon has been in the service for 12 years. The surgeon-general's recommendation has been approved by the Secretary of the Navy and forwarded by him to Congress, with the suggestion that the necessary legislation should be enacted.

Tuberculosis in Cattle.

A series of experiments extending over more than a year has just been completed at the Storrs State Agricultural College, Connecticut, by Professor H. W Conn, having as their object an inquiry into the accuracy of the statements made by Professor Koch in regard to the relation of bovine tuberculosis to that of man and its effect on the dairy herd. His investigations go to prove that the danger of the spread of tuberculosis among human beings through the milk of diseased animals has been exaggerated and that in the earlier stages of the disease when the udder is unaffected the risk from the use of the milk appears to be limited. He, however, points out that it is impossible for the farmer to tell accurately when the udder has become affected, so that, as the only method of freeing herds of cows from the great danger which menaces them is by the segregation of every animal upon which tuberculin reacts, this precautionary measure should be invariably followed.

Modified Quarantine and Yellow Fever.

Dr Alvah H. Doty, health officer of the Port of New York, is about to discuss with Federal officials the subject of quarantine regulations, especially as they bear upon yellow fever coming into New York. He will advise that the Government shall do all in its power to bring about a conference of leading sanitarians who have had experience of yellow fever, and he looks forward to a modification of the existing quarantine regulations Dr Doty holds that as the mosquito is the only known medium of infection the present quarantine regulations in force in New York Harbour are both troublesome and unnecessary, and he maintains that when a ship upon which yellow fever has manifested itself is more than five days from the port of departure removal of those infected removes the fever from the ship, provided there are no yellow-fever-bearing mosquitoes aboard. Dr. Doty made the following remarks in an address before the American Public Health Association dealing with this matter:—"Dr.

---

[1] THE LANCET, April 20th (p. 1174) and Dec. 14th (p. 1704), 1901.

Reed's experiments have not conclusively shown that there may not be some other means than the mosquito by which yellow fever is transmitted. But when these experiments are considered in connexion with the results of our practical experience it is clearly evident that this disease is not contracted by personal contagion or through the medium of clothing, bedding, cargoes of vessels, &c. Therefore I believe we are justified in changing our quarantine regulations to conform to these views, and that such a proceeding is safe and reasonable, particularly as we now have at hand a method which if properly and scientifically carried out, can be depended upon to limit the extension of yellow fever. If the future shows that there are other means of infection it will then be time enough to add whatever restrictions are necessary for the protection of the public health."

Mosquitoes and Dengue.

The *New York Medical Record* of Feb. 8th contained an article on Dengue by Dr. Harris Graham, professor of pathology in the American College, Beyrout, Syria. This article was referred to in THE LANCET of March 22nd at page 855. Dr. Graham made a careful study of, and investigations into, the mode of propagation and the pathology of the disease, and as a result of these researches he claimed that it was caused by a protozoal parasite, and stated that his experiments had convinced him that dengue was conveyed to man by means of a mosquito, apparently of the culex species, which, as in malaria, acted as the intermediary host. The Bureau of the United States Marine Hospital Service having had its attention drawn to Dr. Graham's article has determined to make investigations with the object of testing the value of his conclusions, and has requested that health officers in all parts of the United States will furnish the Surgeon-General of the Marine Hospital Service with early information as to the appearance of dengue in epidemic form in their respective localities, in order that investigators may be early dispatched to the seats of such epidemics.

May 6th, 1902.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Plague.

THE bubonic plague has recurred in Australia, with a varying virulence in the different States. In Sydney it has been very severe, over 80 cases having occurred, with about the average mortality of the previous epidemic—viz., one in three. Two popular actresses were among those who died, and this fact led to Her Majesty's Theatre being closed for a time and quarantined. In Melbourne only one case, non-fatal, has occurred so far. In Brisbane several cases have been notified. A supposed case was isolated at Adelaide but the diagnosis proved to be erroneous. No cases have been reported from West Australia. As regards Sydney the fresh outbreak began gradually. For 15 months the disease was quiescent and it reappeared on Nov. 14th, 1901. Up to Feb. 20th, 1902, 22 cases occurred at varying intervals, from 36 days to one day, and in six different areas. In some areas the nature and source of infection could not be traced; in others a definite local infection from rats was fairly clear. Four produce stores were implicated in the outbreak. The cases afterwards increased in number with few and short intervals. One infected area was largely occupied by Chinese and was highly insanitary. The destruction of rats and cleansing operations are being vigorously prosecuted in all the States. It is difficult to conceive, however, how indifferent the various municipal authorities are to sanitary matters. In Melbourne, for instance, the garbage and refuse are still disposed of in "tips" which are most obnoxious. The corporation imported a destructor which could deal with only about one-fifth of the refuse, but it is not used, it is said, because of the cost. In Sydney recent inspections showed that parts of the city which had been demolished during the first outbreak of plague had been rebuilt in exactly the same insanitary manner and under the very eyes of the municipal authorities.

The Health of Sydney.

The medical adviser to the Metropolitan Board of Water-supply and Sewerage, Sydney (Mr. T. M. Kendall), has furnished his annual report. It stated that the board supplied water to 511,382 persons, of whom only 364,775 were accommodated with a sewerage system. The mor-

mortality from diarrhœa and typhoid fever was lower and that from diphtheria and phthisis was higher. An investigation of 874 cases of typhoid fever reported showed that 31·2 per cent. came from districts unprovided with sewerage, 28·6 per cent. from dwellings unconnected with sewers, 24·3 per cent. from dwellings in which the sanitary fittings were defective, and 15 per cent. from dwellings in which the board's regulations had been complied with. The installation of the sewerage system had undoubtedly diminished the prevalence of typhoid fever. The mortality from this disease before and after the laying down of the sewers had been as follows in the districts named: city of Sydney, before 5·07, after 1·07; Glebe, before 2·5, after 1·8; Darlington, before 4·0, after 0·3; Newtown, before 6·6, after 1·8; Redfern, before 3·6, after 1·0; Waterloo, before 1·2, after 0·9; Paddington, before 2·7, after 0·9; Woollahra, before 2·1, after 0·8.

Hospital Affairs.

The difficulty at the Women's Hospital, Melbourne, to which reference has been previously made, remains unsettled. The resident staff was dismissed and when applications for the positions were invited the two late residents were the only applicants. The committee refused to re-appoint them and Dr. Andrew Shields, formerly Government medical officer, offered his services temporarily and was appointed. The committee now invites applications from men who have been three years at least in practice and offers a salary of £250 per annum.—The report read at the annual meeting of the supporters of the Sydney Women's Hospital showed that 299 in-patients and 1493 out-door patients had been treated. The financial position was satisfactory. The directors intimated that as soon as the new maternity hospital in course of erection was completed the Women's Hospital would be amalgamated with it.—The twenty-second annual report of the Sydney Hospital for Sick Children stated that 536 in-patients had been treated. Of this number 314 were discharged cured, 72 were relieved, 46 were discharged unrelieved, 60 died, and on Dec. 31st there were 44 remaining in the hospital. In the diphtheria cottage there had been admitted 197, making, with five remaining from the previous year, a total of 202 patients under treatment. Of these 155 were discharged cured, 36 died, and on Dec. 31st there were 11 remaining in the wards. In moving the adoption of the report the Premier drew attention to the very large amount of money spent by the State in assisting hospitals. Last year the Government grant to various hospitals amounted to £227,000, and he deemed that the community did more than any other country in the world in supporting charitable institutions. The Government had also granted a very fine site for a new children's hospital and had undertaken to drain it. It overlooked Centennial Park, Moore Park, and Botany Bay and could not be built out.—The annual report of the Prince Alfred Hospital, Sydney, stated that the statistics of the first year's work were as follows:—Remaining in hospital on Dec. 31st, 1900, 223; admitted during the year 1901, 3216; total under treatment, 3439. Of these 1848 patients were cured, 725 were relieved, 268 were unrelieved, 360 died, and 238 remained in hospital on Dec. 31st, 1901. The rate of mortality per cent. (deducting 61 deaths which occurred within 24 hours of admission) was 9·29.—The annual report of the Sydney Hospital showed that the patients remaining in hospital on Dec. 31st, 1900, numbered 286; patients admitted during 1901, 3951. Total under treatment, 4237. Discharged cured, 2467; relieved, 873; unrelieved, 165; died, 428; remaining in hospital on Dec. 31st, 1901, 304; percentage of mortality on admissions, 10·9. Improvements had been effected in the buildings by the erection of the Nightingale wing and operating theatre—now equal to anything in the southern hemisphere. The Government had voted an additional sum of £2500 for further improvements, including the furnishing of the Nightingale ward and a new casualty room. Reference was made to the danger of admitting phthisical patients to the general wards and the efforts made to establish a separate institution for their treatment. The pathological department of the hospital had proved of great use as a help to the diagnosis of cases in the wards. The laboratory of pathological chemistry was now equipped with apparatus which rendered it possible to make use of the more modern discoveries in physiological and pathological chemistry in their application to the improvement of diagnosis, prognosis, and treatment in many cases of disease which were before surrounded by almost impregnable difficulties and fallacies. It that to it belonged the honour of being the pioneer hospital of Australia, perhaps of the southern hemisphere, in introducing modern chemical methods in diseases of the stomach and metabolism generally. In the skiagraphic department a large number of cases had been treated, 263 cases having been submitted to the Roentgen rays.—A new hospital has been established in Sydney called the King Edward Hospital. It is situated at Miller's Point and is specially for seamen. It has been started very quietly and many doubt the need for it seeing that the Prince Alfred Hospital and other hospitals are being enlarged.—The committee of the Melbourne Hospital has appointed delegates to confer with delegates from other hospitals to fix a standard of efficiency for trained nurses and if possible to appoint a conjoint board of examiners and to decide on a recognised system of examination. The committee also decided in future to import all the drugs required direct.

The Profession and the Friendly Societies in New South Wales

As has been previously mentioned, friction has existed for some time between the friendly societies in New South Wales and their medical officers, or more strictly the New South Wales Branch of the British Medical Association. Matters are rapidly reaching a crisis. At the annual meeting of the Friendly Societies' Association held on March 12th the matter was referred to. The annual report stated :—

> During the year under review the attention of this association has been directed by an affiliated society to the action of the British Medical Association in practically boycotting the society referred to. The majority of societies for several years past have enjoyed an uninterrupted career of mutual understanding between the members and the surgeon, but if this new issue, the wage-limit question, is pressed it cannot conduce to the maintenance of the harmony that has hitherto existed. The following notice of motion was referred to a committee to report: "That it is desirable to place before all candidates for State election the question if they favoured the introduction of a measure whereby medical practitioners would be compelled to meet in consultation any duly qualified medical man and regulate fees for attendance and consultations." The committee met and took a quantity of evidence but the State elections being then in full swing it was too late to make any recommendations dealing with the above notice of motion.

The President said further :—

> Unless they could make some compromise with the British Medical Association he could not help saying that he foresaw trouble looming in the distance. The question of the wage-earning limit was a serious matter and could not be regarded too lightly by this association. The action of the doctors in his opinion would be to destroy a cosmopolitan character of our societies. They considered no man's financial position any barrier to their membership. That a man with his income of thousands was equally entitled to membership in their orders as a man whose earnings amounts to £200 or less, that being the limit fixed by our worthy friends "the doctors" to admit as financial members of a society. The medical fraternity were doing their utmost to keep out an element which was conducive to the well being of the society. Very many of the moneyed members, while paying their contributions had not joined for any benefits that they may be entitled to, and the same will apply to the doctors. Very few of such members have enlisted the services of the lodge doctor and he challenged the profession to say otherwise. Their societies were not open to distinction or class. The admission of the rich and the poor was essential to their success, both financially and intellectually. Roughly estimated there were about 70,000 or 80,000 members of various orders in New South Wales and if a central medical board was formed sufficient funds could be raised annually to pay salaries to doctors and distribute them in all parts of the State. Other difficulties such as meeting in consultation could easily be overcome by legislation, but he should be very loth to interfere in the harmony now existing, but would be forced to do so if this wage-earning limit were persisted in.

The matter was discussed by the meeting and it was agreed that the action of the British Medical Association in boycotting the Australian Natives' Association was inimical to the interests of friendly societies and that this resolution should be forwarded to the secretary of the British Medical Association. It was also decided that a special meeting should be held this month to consider the question raised by the doctors. The New South Wales Branch of the British Medical Association also discussed the subject at its last meeting and carried a motion—

> That the resolution of August 31st, 1900, declaring the Australian Natives' Association to be a society inimical to the interests of the medical profession, be adhered to.

The Australian Natives' Association is determined to make the question a public one and, according to its secretary, "will fight it to a finish." He observes that at the inception of the Australian Natives' Association the British Medical Association demanded that a wage-limit of £200 per annum should be fixed. After some consideration the wage-limit was conceded and still the British Medical Association boycotted the Australian Natives' Association. At its inception the Australian Natives' Association had only one branch with 32 members; now it had 35 branches and 2700 members. Out of nearly 1200 medical practitioners registered in the State of New South Wales only 300 are members of the British Medical Association.

Obituary.

Dr. George Goode of Camden, New South Wales, died recently. He was born in Ireland in 1843 and took his M.A. and M.D. degrees at Dublin University. He was for some years in the New Zealand Investigation Service and went to Camden in 1875. After residing there for 10 years he removed to Orange, but after a few years resumed practice at Camden. He was a brother of Dr. J. Goode, of Macquarie-street, Sydney, and was well known and popular with the profession.

April 7th.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The following medical and surgical degrees were conferred on May 8th :—

Bachelor of Medicine.—H. P. Bradley and B. L. Thurlow, Gonville and Caius; and J. M. Brydone, Jesus.

Bachelor of Surgery.—J. P. Hedley, King's; G. R. Wilson, Trinity; A. S. Bradley, G. L. Crimp, G. P. D. Hawker, J. E. B. Snell, and B. L. Thurlow, Gonville and Caius; J. M. Brydone, Jesus; F. E. Shipway, Christ's; H. C. Brown, A. F. Elliott, and H. J. Shone, Emmanuel; and C. H. Sedgwick, Sidney Sussex.

The Registrary calls the attention of candidates for medical and surgical degrees to the new regulations for the Third Examination for the degree of M.B. which will come into force next term and points out that all such candidates, with the following exceptions, are now subject to those regulations :—

1. Students who have already passed one part of the Third Examination. Students who have passed in surgery and midwifery (old III. M.B., Part I.) are required to satisfy the examiners in section (3) only of the new Part II. (physic). Students who have passed in physic (old III. M.B., Part II.) are required to satisfy the examiners in sections (1) and (2) only of the new Part II. (surgery and midwifery).
2. Students who shall have passed both parts of the Second Examination before October next. These students are still permitted to present the same certificates on admission to Part I. of the Third Examination as would have been required from them on admission to Part I. under the old regulations, and to present the same certificates on admission to any section or sections of Part II. as would have been required from them on admission to Part II. under the old regulations.

Students who have been admitted to, but have not passed, either part of the Third Examination must, either before, after, or together with Part II., pass the new Part I. (pharmacology and general pathology), but they require no new certificates for admission either to this part or to the section or sections of the new Part II. corresponding to the part of the old Third Examination to which they have already been admitted. A special examination in pharmacology and general pathology will be held on June 9th, 1902, the ordinary examination for Part I. will be held in December, 1902, and in June and December of future years.

UNIVERSITY OF DURHAM.—At the convocation held on April 26th, the following degrees and diploma were *conferred* :—

Doctor in Medicine.—Laurence James Blandford, M.B., B.S. Durh.; Leopold Stanley Davison, M.B., B.S. Durh.; Richard Henry Dix, M.B., B.S. Durh.; Henry Adamson Fielden, M.D., B.S. Durh.; John Reginald Fuller, M.B., B.S. Durh.; Edward Walter Joscelyne, M.B. Durh.; Eliot Swainston, M.B., B.S. Durh.; and David Henderson Weir, M.B., B.S. Durh.

Doctor in Medicine for Practitioners of 15 years' standing.—Edward Harris Armitage, M.R.C.S., L.R.C.P., D.P.H.; Charles William Josceline Bell, M.R.C.S., L.R.C.P.; Albert Bothay, M.R.C.S., L.R.C.P., L.S.A., D.P.H.; Edward Joseph Day, M.R.C.S., L.S.A.; Ambrose William Fairles, M.R.C.S.; Thomas Frederick Gardner, M.R.C.S., M.R.C.P., L.S.A.; Frederick Charles Goodwin, M.R.C.S., L.R.C.P., D.P.H.; William Gosse, M.R.C.S., L.R.C.P.; Robert Rankin Hunter, M.B., M.S. Glasg., M.R.C.S.; Richard John Morris, M.R.C.S., L.R.C.P., L.S.A.; John Latimer Parke, L.K.Q.C.P. Irel., L.F.P.S. Glasg., L.S.A., D.P.H.; James Williamson Patrick, L.R.C.P. & S., George Frederick Pollard, M.R.C.S., L.S.A.; Alfred Tom Rimell, M.R.C.S., L.R.C.P.; and John Rogerson, L.R.C.P. & S. Edin., L.F.P.S. Glasg.

Master in Surgery.—Joseph William Leech, M.D., B.S., F.R.C.S., and William Hunter Richards, M.B., B.S.

Bachelor in Medicine (M.B.).—Ernest Bertram Appleby, William Robert Davidson Daglish, Mary Evelyn De Rusett, Henry Wallace Furnivall, James Alfred Giles, and James Herries Graham, College of Medicine, Newcastle-upon-Tyne; Ivon Henry Skipwith Hawes, St. George's Hospital; Konrad Manson, College of Medicine, Newcastle-upon-Tyne; Lucy Selina Molony, London School of Medicine for Women; Robert William Nevin, Henry Reah, Ralph Stuart Renton, Hermann Heinrich Ruffmann, and Alfred Henry Proctor, College of Medicine, Newcastle-upon-Tyne; Godfrey De Bec Turtle, King's College; Ralph Thomas Vaux, College of Medicine, Newcastle upon Tyne; Marmaduke Conleux Wetherell, Guy's Hospital; and Hugh [illegible] and Thomas Wilson, College of Medicine, Newcastle-upon-Tyne.

Bachelor in Surgery (B.S.).—Ernest Bertram Appleby, William Robert Davidson Daglish, Mary Evelyn De Rusett, Henry Wallace Furnivall, James Alfred Giles, and James Herries Graham, College of Medicine, Newcastle-upon-Tyne; Ivon Henry Skipworth Hawes, St. George's Hospital; Konrad Manson, College of Medicine, Newcastle-upon-Tyne; Lucy Selina Molony, London School of Medicine for Women; Robert William Nevin, Alfred Henry Proctor, Henry Reah, Ralph Stuart Renton, and Hermann Heinrich Ruffmann, College of Medicine, Newcastle-upon-Tyne; Godfrey De Bec Turtle, King's College; Ralph Thomas Vaux, College of Medicine, Newcastle-upon-Tyne; Marmaduke Cordeux Wetherell, Guy's Hospital; and Hugh Widdas and Thomas Wilson, College of Medicine, Newcastle-upon-Tyne.

Diploma in Public Health (D.P.H.).—Charles Vincent Dingle, M.D., B.S., B.Hy. Durh.; Robert Ayton Dunn, M.D., B.S., D.Hy. Durh., M.R.C.S., L.R.C.P.; Alfred Reid, M.R.C.S., L.R.C.P.; and Robert Walker, M.B., B.S. Durh., M.R.C.S., L.R.C.P.

Conjoint Examinations in Ireland by the Royal College of Physicians and Royal College of Surgeons.—At the examination for the Diploma in Public Health the following candidates were successful:—

William E. Burton, M.R.C.S. Eng., L.R.C.P. Lond.; Frederick I. de Lisle, L.R.C.P., L.M. Edin.; Edward G. Gibbs-Smith, L.R.C.P. Irel., L.S.A. Lond.; L. R. More O'Ferrall, F.R.C.S. Irel.; Rowan M'Combe, L.R.C.P. & S. Irel.; Michael M'Grath, L.R.C.P. & S. Irel., Alex. G. Robb, M.B., B.Ch. R.U.I.; and Arthur Williams, L.R.C.P. & S. Edin.

Oysters and Typhoid Fever.—The Sanitary Committee of the Cornwall County Council has decided to recommend that the county council shall petition the Local Government Board and the Board of Trade to allow an addition to the by-laws of the county council to prevent the laying of any oyster or any other shell-fish on grounds within the council's area that may be, in the opinion of the council, contaminated with sewage or other objectionable matter.

The late Dr. R. T. Pearse.—Dr. Reginald Thomas Pearse died at his residence in Dawlish on May 5th in his 69th year. He was born at Bradninch, Devon, and received his medical education at the Bristol Medical School, taking the qualification of M.R.C.S. Eng. and L.R.C.P. Edin. in 1856 and 1859 respectively. He graduated as M.D. of St. Andrews University in 1889. Dr. Pearse practised for many years in Cathedral-road, Cardiff, and held several appointments in that town. He had recently resided at Dawlish for the benefit of his health.

A Novel Patent.—An American inventor has patented a "burial vault" which appears to consist of a kind of outer coffin having a groove or channel all round the upper margin of the main portion or body to contain a sealing material, while the lid has a flange which dips into the sealing material. A coffin of the ordinary shape stands inside. An engraving and the specification will be found in the *Official Gazette* of the United States Patent Office issued on April 29th, 1902. It is not stated whether this contrivance is intended for the temporary custody of a corpse or for permanent sepulture; in the latter case it would, of course, be at variance with accepted hygienic principles.

Freemasonry.—*The Rahere Lodge.*—A meeting of the Rahere Lodge, No. 2546, was held at Frascati's Restaurant, Oxford-street, W., on May 13th, W. Bro. P. S. Abraham, M.D. Dub., W.M., being in the chair. Bros. Harke, Yetts, and Dunn were admitted to the third degree; Messrs. Thomas B. A. Haggard and Charles J. Ogle, M.R.C.S. Eng., L.S.A., were initiated into Freemasonry; while W. Bro. T. F. Vaisey, M.R.C.S. Eng., L.S.A., was elected a joining member of the Lodge. W. Bro. G. H. R. Holden, M.D. Cantab., was unanimously elected W.M. for the ensuing year, while W. Bro. Clement Godson, M.D. Aberd., was re-elected treasurer. A number of brethren afterwards dined together.

The Royal Institution.—Exploration and Climbing in the Canadian Rocky Mountains formed the subject of the Friday evening discourse delivered at the Royal Institution on May 9th by Professor J. Norman Collie. His address, which was illustrated by a very large number of lantern slides, included a remarkable account of a member of his party being very little the worse after falling some 60 feet down a crevasse and becoming wedged in a most difficult position between two perpendicular walls of ice. Professor Collie claims to have corrected some misdescriptions in the geography of previous explorers, especially as regards the situation, and even the existence, of two peaks to which some 80 or more years ago David Douglas assigned the names of Mount Brown and Mount Hooker, after his friends the botanists Robert Brown and Sir William Jackson Hooker respectively. Professor Collie also described a mountain from which there descend rivers that flow into three oceans—namely (1), the Columbia river which falls into the Pacific Ocean; (2) the Athabasca river which empties itself into the Great Slave Lake and is continued as the Mackenzie river, falling into the Arctic Ocean; and (3) the Saskatchewan river which empties itself into Lake Winnipeg and, continued under the name of the Nelson river, ultimately falls into Hudson's Bay, an offshoot of the Atlantic Ocean.

Cruelty to Frogs.—At Clerkenwell Police-court on May 9th a fish and reptile dealer of Rosebery-avenue, Clerkenwell, was charged with causing unnecessary suffering to certain reptiles—namely, frogs. The evidence showed that a large number of frogs were massed together in a fish-bowl in the defendant's shop window. An inspector of the Society for the Prevention of Cruelty to Animals said that there were only two inches of water in the bowl; he had the frogs counted and found that there were 109, of which 20 were dead and others were in a dying condition. The defendant admitted to him that the frogs were overcrowded. The magistrate ordered the defendant to pay a fine of £2 and £2 2*s.* costs.

Medical Golf Tournament.—The fifth annual tournament will be held on May 29th at Northwood, by kind permission of the Northwood Golf Club. The regulations are the same as those of last year—viz., 18 holes match play *v.* Bogey, competitors being divided into two classes: (1) handicaps of 12 and under and (2) over 12. Members of the Northwood Club deduct two from their handicap. First and second prizes and a prize for best last nine holes *v.* Bogey in each class. Foursome sweepstakes *v.* Bogey will be played during the afternoon. No match may be started later than 3.15 P.M.; no previous play allowed on the day. Entries, stating lowest handicap and inclosing 5*s.* entrance fee, should be made before May 29th to the honorary secretary, Mr. Rolf Creasy, Windlesham, Surrey.

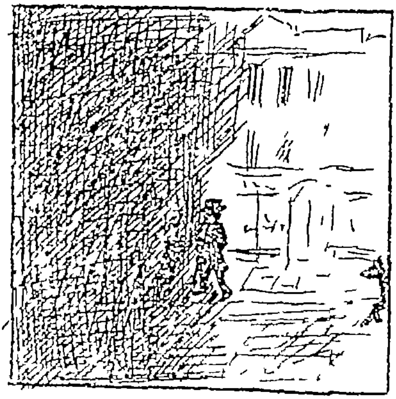
Surgical Splints as a Placebo.—At the Exeter Police-court on April 28th a woman appeared with her arm in splints and charged a lad, aged 10 years, with attacking her with a hatchet. The assistant house surgeon stated that the woman came to the Devon and Exeter Hospital for treatment. They could find nothing the matter with the arm but placed it in splints, as persons in similar cases would often say that they had been refused treatment if something of the sort were not done. The magistrates dismissed the case and the mayor said that the surgeons had no doubt acted in a manner which they thought for the best, but he suggested that it would be wiser not to pacify people by putting on splints when there was no necessity, because in this case the patient had used the splints for the purpose of getting a warrant against the boy, the magistrates believing that the case was more serious than it actually was.

A Notable Record of a Country Practitioner.—Mr. Charles W. Izod, M.R.C.S. Eng. (1846), L.S.A. (1847), L.M. Dub., of Esher, Surrey, after 55 years' practice will retire in June next. This gentleman went to Esher in 1847 as surgeon to the Household at Claremont, near Esher, of the King of the Belgians, Leopold I., and subsequently retained the post under his niece, the late Queen Victoria, till her death on Jan. 22nd, 1901. He now holds a similar position under the Duchess of Albany. He was present at the death at Claremont on August 26th, 1850, of the abdicated King of the French, Louis Philippe, and later at the death of his wife (the daughter of Ferdinand IV., King of Naples) and at the death of the Duchesse de Nemours, their daughter-in-law, besides attending other members of the French Royal Family.

Miss Weston's Work in the Royal Navy.—A meeting was held in Exeter Hall, London, on May 6th to hear from Miss Agnes E. Weston the annual account of her work in the Royal Navy. Miss Weston stated that the number of sleepers at the Royal Sailors' Rests at Portsmouth and Devonport during the past year had been 246,696, an increase on the preceding year of 671. The receipts had been £21,626, an increase of £671. At Devonport building extensions had been begun to be dedicated to the memory of "Victoria the Good." 9048 temperance pledges had been taken, an increase of 585, and 142,668 parcels of literature weighing 37 tons had been distributed among the fleets. The circulation of *Ashore and Afloat*, edited by Miss Wintz, had reached 599,825 copies, an increase of 15,825; and, together with the *Blue Backs*—Miss Weston's monthly letter—the number reached was 1,266,505 copies, the military edition being distributed amongst the army, notably in South Africa.

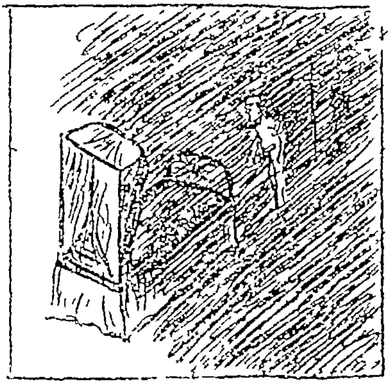
he finds that when opening them suddenly at times when his mind is not specially occupied all kinds of fantastic designs in black and white appear before the eye, as if he was looking through a kaleidoscope, and remain for a few seconds and gradually fade away. The figures shown are often of familiar animals, fleur-de-lis, black battlements, &c., and are always mixed up with a section of a "chess board." A wall-paper designer might get some profit from glaucoma. On waking from sleep objects appear visible about which the patient has not recently thought or dreamt though they were once much in his mind. A woman's costume fixed on a wire stand has more than once appeared in this way and has only very gradually vanished. A most peculiar instance, however, is illustrated below. The patient being awakened by his wife bringing up a cup of tea is conscious before receiving the cup that the space between the door and the bed is occupied by the apparition of himself as he looked 20 years ago—dressed in cricketing flannels, necktie flying in the wind, the face being flushed and indicating the joy of life. This apparition continued visible some time after he had received the cup of tea and had informed his wife of what he saw (Fig. 3.)

FIG 2.



Market-street, Manchester is here shown. The patient's son, who leads him, remarks that the street is more than usually crowded So far as his (the patient's) eyes tell him, however, it presents a deserted appearance, as in this sketch

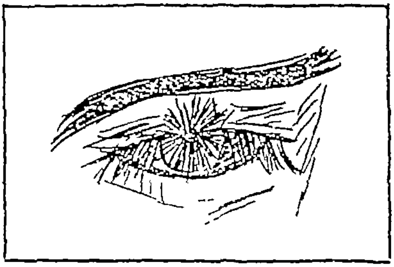
FIG 3.



The patient is lying in the bed shown The figure standing at the foot is a sudden apparition of himself when 20 years younger

The gummy feeling of the eyelids to which reference has been made may be slightly relieved by bathing with warm water and is an annoyance worth bearing patiently But a trick played by the eye, as shown in the following sketch (Fig 4), seems to go a little too far towards the region of insult. The patient's eyelashes now and then seem to form themselves into a kind of wheel which will revolve with considerable speed for several seconds, the lashes being magnified to about three times their right size.

FIG 4



Wheel appearance caused by the eyelashes.

The medical dictionaries and handbooks on eye diseases give very scanty accounts of glaucoma, but it seems to be looked upon as incurable by oculists of great experience. Again and again, always in kind and sympathetic tones, comes the same best possible advice "Your case is hopeless, keep up your spirits and general health." He who has done all things well does for the asking give a man power to see the cheerful and even humorous side of blindness. Still, the particular joys of glaucoma are not always apparent and the sympathetic paralysis with which it is accompanied is sympathy not easily appreciated.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.

ANNUAL GENERAL MEETING

SIR WILLIAM H BROADBENT, Bart., presided on March 25th over the third annual general meeting of the members and subscribers of the Medical Graduates' College and Polyclinic at 22, Chenies-street, London

The third annual report of the council began by pointing out that the fact that new names were added almost daily to the register showed that the Polyclinic filled a long felt want. Many of the members had frequently availed themselves of the opportunity afforded them for obtaining an expert opinion upon cases of unusual rarity or of peculiar interest The recommendations of members who had attended practical classes had resulted in the attendances being considerably augmented The number of members and subscribers for 1901 was 825. Most interesting discussions had taken place at meetings of the special committees dealing with leprosy, yaws, climatology, and tuberculosis and much useful information had been brought forward. It was announced that there were in course of constitution two new special committees for the investigation of cancer and vaccination. In October, 1900, short courses of lectures on special subjects were *inaugurated and* the arrangement worked *so well that for the year 1901* the number had been doubled. The scale of charges for the practical classes had been revised and the change had been much appreciated by the members. The vacation session of three weeks held in September proved a great success. The determination had therefore been arrived at to hold a similar course again Arrangements had been completed whereby members could obtain instruction in operative surgery The council felt assured that in the course of time the consultation department would constitute a very special and much-utilised feature of the college work. The report contained a table showing the nature of the investigations which had been conducted in the laboratory during the past year and

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Poor-law Nursing.

The departmental committee appointed by the President of the Local Government Board to inquire into the question of the nursing provision in Poor-law infirmaries in England has been engaged during the last three months taking evidence and carrying on investigations. It is expected that the report of the committee will be ready early in June. The chairman of the committee is Mr. J. Grant Lawson, M.P., Parliamentary Secretary to the Local Government Board, and the secretary is Mr. H. R. Duff of the same Department.

HOUSE OF LORDS.

Monday, May 12th.

The Shop Hours Question.

Lord Avebury moved the second reading of the Shops Early Closing (No. 2) Bill and explained that the measure contained certain safeguards upon the absence of which from the Bill introduced earlier in the session and rejected on second reading the Prime Minister had commented. According to the present Bill two-thirds of the shopkeepers must memorialise the local authority before the latter passed a regulation for the closing of shops and this regulation must obtain the consent of the Home Office and be submitted to Parliament. His Lordship urged that legislation on this subject was greatly needed. In many cases shop assistants, male and female, were working from 80 to 90 hours per week, hours grievously injurious to health.—The Earl of Wemyss moved the rejection of the Bill.—The Earl of Morley and the Lord Chancellor raised the point of order that this Bill was practically the same measure as their lordships had rejected earlier in the session and therefore was not competent.—The Marquis of Salisbury, without going into the merits, supported this view of the matter.—The previous question was then moved and agreed to, the result being that no more will be heard of the Bill during the present session

Accidents with Celluloid.

Lord Saltoun asked the Government in view of the fact that celluloid was a highly inflammable and sometimes explosive substance, and that it was used freely in articles of attire, such as combs and collars, whether they would cause such modification to be used in its manufacture or place such regulations and restrictions upon its sale as would render impossible the recurrence of the many serious burning accidents which had already resulted from the unrestricted sale of this article. His lordship also quoted from an article in The Lancet dealing with some experiments on the subject.—Lord Belper, replying on behalf of the Home Office, said that he was informed that if celluloid was properly manufactured and free from impurities it would not take fire except at a very high temperature indeed—that was to say, it would only smoulder at a temperature of 440° F. and would not burst into flame until a temperature of 550° F. was reached. The accidents to which the noble lord had referred must have been due to the impurity of the materials used in the manufacture of the celluloid. The Secretary of State, having very carefully considered the matter and feeling the greatest possible sympathy with those who had suffered from the accidents, did not see his way to interfere by legislation with the sale of celluloid.

HOUSE OF COMMONS

Thursday, May 8th.

A Scottish Medical Appointment.

Mr. Harmsworth asked the Lord Advocate whether he was aware that on March 8th last the County Council of Caithness appointed a duly qualified medical practitioner to be medical officer of health of the county, and that this practitioner had not yet entered upon his duties consequent on delay on the part of the Local Government Board in intimating whether he would be allowed to have consulting practice; and whether he could state when the decision of the department would be communicated to the authorities at Caithness.—The Lord Advocate replied: On March 12th the Local Government Board was informed that the County Council of Caithness had appointed a county medical officer with permission to engage in consulting practice. The Local Government Board did not interfere with the appointment or hinder the new officer entering on his duties It was necessary, however, to consider whether the grant in aid of the cost of medical officers should be payable to the county council in respect of this appointment. The rule is that where the medical officer engages in consulting practice the grant is not given unless the Secretary for Scotland is satisfied that there are exceptional circumstances justifying this arrangement. The necessity of considering these circumstances in this case caused some delay but the county council has now been informed that the grant will not be given

The Butter Standard.

Sir Edward Strachey asked the President of the Board of Agriculture whether he would immediately after May 15th take such steps as might be necessary to test the value of the standard for butter set up by the Board of Agriculture, so that the uncertainty now existing whether after that date milk blended butter containing a higher percentage of moisture than permitted by the standard could still be sold might be determined.—Mr. Hanbury replied: It has not been the practice of the Board to anticipate the action of local authorities for the purpose of testing the effect of statutes, and in view of the full powers of local authorities I do not think that any special necessity for doing so arises in this case. The authority given by statute to the Board has been fully exercised in issuing the regulations.

Friday, May 9th.

Small-pox Hospital at Hanworth.

Sir Frederick Dixon-Hartland asked the President of the Local Government Board whether he was aware that a small-pox hospital was being erected at Hanworth, Middlesex, on land the surface water from which drained into the Thames at Hampton immediately above the intakes of the Southwark and Vauxhall Water Company, the Grand Junction Water Company, and the West Middlesex Water Company; whether he was aware that the site on which the building stood was at times under water from four to nine inches; and, seeing that it was contrary to the regulations of the Local Government Board issued in August, 1900, to build on a site where 400 persons reside within a quarter of a mile of the building, over 1000 within half a mile, and 3000 just outside that radius, whether he would take any, and if so what, steps to prevent the danger to the neighbourhood and London which was shadowed forth.—Mr. Long replied: I am aware that a temporary small-pox hospital is being erected at Hanworth for the use of the urban districts of Hampton, Teddington, and Hampton Wick and complaints have been made to me with regard to it. I can only require the observance of the regulations referred to in the third paragraph of the question in cases in which the cost of the hospital is to be defrayed out of borrowed money. In the present instance I understand this is not proposed and I have therefore no authority to interfere. Having regard, however, to the allegations made, I have thought it desirable to instruct two of the officers of the department to visit the site and to report to me fully on the subject, and I have given instructions accordingly.

Monday, May 12th.

The Butter Standard.

Mr. O'Shaughnessy asked the President of the Board of Agriculture whether, in view of the fact that the Departmental Committee appointed to inquire into the standard of water in butter reported that many witnesses declared Irish salt firkin butter would be injuriously affected by any limit applicable to all other butters, as on account of its long-keeping qualities it necessarily contained a higher percentage of moisture than was found in any other butter, and considering that several public bodies in Ireland were protesting against the new regulations as applicable to this class of butter, he would consider the matter of fixing a separate standard for it.—Mr. Hanbury said: I am not aware that salt butter will in any way be injuriously affected by the new standard, nor was any evidence, I believe, given to that effect. The brine butter, to which hot brine is added instead of salt, with the result of largely increasing the percentage of water, will, no doubt be affected, but the practice has for some time been dying out and at a meeting of the South of Ireland Butter Merchants' Association held in Limerick a day or two ago it was, I understand, resolved to recommend the use of dry salt instead. I believe such a course will do much to add to the price of the butter and in any case the Irish Department agreed with me in fixing the standard of water in butter which is the same in both countries.

Sir Edward Strachey asked the President of the Local Government Board whether his Department had decided that the substance known as milk-blended butter was an impoverished article of food as defined in Section 1, Part VII, of the Sale of Food and Drugs Acts, 1899, and whether he would take such steps as might be necessary to test the value of the standard for butter set up by the Board of Agriculture under the powers given to his Department by Section 2 of the same Act.—Mr. Long replied: Section 1 of the Act referred to imposes penalties on persons who import certain adulterated or impoverished articles, but the Local Government Board have no power to decide what is an impoverished article for the purposes of this section. As regards the second part of the question the *Board of Agriculture* have, in the exercise of their statutory powers, made regulations for determining the proportion of water in butter which raises the presumption that it is not genuine. I could not undertake to direct that samples should be procured with a view of testing the value of the standard thus set up.

Wednesday, May 14th.

The Butter Standard.

Mr. John Redmond asked the President of the Board of Agriculture whether his attention had been called to the paragraph in the interim report of the Butter Regulation Committee, in which it was stated: "The committee, moreover, understand that the vendors of this type of butter containing water in excess of the proposed official limit would be legally protected provided that a sufficient disclosure is made to the purchaser, and this consideration finally decided the committee to recommend the single limit and leave it to the vendors of Irish salt firkin butter to protect themselves in the simple manner indicated"; and whether, in view of the crisis in the butter trade, he would say whether the legal advisers of the department had been consulted upon this matter and if they agreed with the view expressed in that paragraph.—Mr. Hanbury replied: I have no power under the statute to do more than state what the standard should be. In the opinion of my legal advisers the effect of fixing a standard does not necessarily prevent the disclosure of an excess of water in butter being a sufficient defence, but, of course I cannot say what view the courts may take. In any case, the report of the committee was intended to do no more than safeguard for a reasonable period an old fashioned industry in which brine is used for preserving butter. In any steps that I have to take to prevent the fraudulent addition of water to butter in which the makers and sellers of both countries are interested, the view taken by the committee as regards the use of brine as a preservative of butter will of course be recognised

Mr. Redmond: Do I understand that in the opinion of the legal advisers disclosure will be a sufficient protection?—Mr. Hanbury: That is so.

ROYAL COMMISSION ON ARSENICAL POISONING.

Evidence by Mr. Fletcher Moulton.

The Royal Commission on Arsenical Poisoning held a meeting for the examination of witnesses on May 9th, in the Westminster Palace Hotel, Victoria-street S.W. In the absence in America of Lord Kelvin the chair was taken by Sir William Hart Dyke, M.P., the other members of the Commission present being Sir William S. Church, Professor Thorpe, Dr. B. A. Whitelegge, and Mr. Cosmo Bonsor with Dr. G. S. Buchanan of the Local Government Board, secretary.

Mr. J. **FLETCHER MOULTON**, K.C., M.P., examined by Sir W. **HART DYKE**, said that on the occurrence of what had come to be known as the Manchester scare he was consulted next after Mr. Gordon Salamon and the whole case was put before him by Mr. Groves, M.P., and when it was decided that a committee of experts should be formed he had the question of the most suitable members for the committee put before him. Almost immediately after the discussion between Mr. Gordon Salamon, Mr. Groves, and himself the members of the committee were selected and he, with the others, proceeded to Manchester to investigate matters on the spot. It became perfectly clear to them that the mischief was very widely spread. The Manchester brewers were for the most part incredulous as to the possibility of there being any serious arsenical poisoning. It was a thing so utterly without precedent that at the time when the committee arrived the brewers believed that it was something that had gone wrong with one particular brewer's product and they had no appreciation of the extent to which it was common to the whole trade. The consequence was that the first effort of the committee was to make the whole of the brewers realise that the mischief was not confined to any one brewer but that a large number of brewing houses must necessarily be implicated in it because it came from sugar which was largely used in the neighbourhood. The object of the committee at first was by means of making the brewers realise the scale of the calamity to get some measures adopted immediately which would put a stop to all future mischief. He wished to put that before the commission because in his opinion there never was vacillation or change of view on the part of the members of the committee of experts with regard to the tests used or the measures to be adopted, but the problem of defining some immediate step, some test which would be practical and which would prevent future mischief, was a different task from the deciding what should be the precautions to be used in future when the object was not to stop the possibility of the present danger but to give absolute security for the future. As to the early discussions as to the measures to be taken the members of the committee always kept in mind that these were emergency precautions. When the case had been put before the brewers the committee received every assistance from them. He did not believe that from that time any beer got out which could possibly cause any mischief except perhaps by accident. He thought that he remembered one case coming before the courts in which beer had been sold subsequently to the announcement of precautionary measures, but it was obviously an isolated case and due to confusion between two casks. But substantially from the time that the brewers became aware of the gravity of the matter and what steps ought to be taken by way of precaution all further evil, he thought, ceased. As president of the committee he desired formally to present to this Commission its final report. The committee very soon came to the conclusion that although the mischief was substantially due to the Bostock sugar there was another source of arsenic in beer, namely, the malt. He was bound to say that all other sources seemed to be capable only of producing infinitesimal quantities of arsenic in beer. But the malt was obviously a very serious question and the committee resolved that it would not give a final report until there had been a most searching examination of all the materials used in beer to discover the possibility of arsenical contamination. For the purposes of this report there had been an amount of careful analysis far beyond anything in his experience. The analyses pointed to a very large amount of arsenic in certain portions of malt in the culms and also a considerable amount in the skin of malt. He thought this came as a surprise to every one of them. He remembered Sir Edward Frankland producing at the Royal Institution some crystals of arsenic which he got in the air of London which he attributed to the burning of Midland coal in large quantities. The English method of malting differed from that used in some countries in that the direct products of combustion had access to the grain and in this way arsenic was deposited upon it. In the report there were analyses of specimens of malt which showed a quite considerable amount of arsenic. In this connexion he wished to speak of the impression made upon his mind as a mere observer and not at all as a person entitled to speak from a medical point of view by the close resemblance which all medical men found between the neuritis which characterised this epidemic and the alcoholic neuritis which had never been attributed to arsenic. The proceedings left upon his mind a suspicion that arsenic had played a considerable part in what was called the alcoholism produced by beer and that probably that was due to the fact that this contamination in malting had been very common in past years and that small as the contamination was it might have, in certain constitutions, produced morbid effects. That was the suspicion produced in his mind and he did not think that it was a suspicion which should be completely abandoned because of theoretical arguments as to the smallness of the contamination. One thing that made him cling to the suspicion was the peculiar irregularity in the connexion between the quantity of beer drunk and the arsenical poisoning. There was no doubt in his mind that people who must have drunk very large quantities of beer contaminated by arsenic did not suffer. The peculiarity of this case was that they knew accurately when and to what extent the arsenic passed into circulation. They knew to a week when the arsenically-tainted sulphuric acid was sent to Messrs. Bostock; they used nothing but that; and they knew the quantities of sugar which they produced with it. They knew the localities where the sugar was used, and they had therefore for something like nine months the certainty that fairly heavily-charged beer was sold. They knew the breweries where the beer was sold. Now he inquired as to the employés of the breweries, especially one brewery, at which the committee obtained very complete information upon every point. It was notorious that the employés of breweries consume a large amount of beer and in this particular case with one exception none of them had suffered. The impression that came upon him was that the more poorly-fed people suffered rather than the people who were most alcoholic, who took most beer. In the cases which he saw there were a great number who showed no evidence of extreme alcoholism. He did not think that want of food determined it entirely and the impression left upon his mind was that constitutional peculiarities would make a great difference in the susceptibility to poisoning by these small quantities. If, therefore, they combined the very irregular influence of constitutional peculiarity with the possibility that there had been for years a small contamination due to the difficulty of malting, he should not be surprised if the fact that the attention of the brewing public had been called to it, so that malt would no longer be allowed to be so contaminated, should make a very great difference in the presence of this alcoholic neuritis which had been so associated with it. He was only giving the view of an onlooker, not of an expert. He could not speak of his own knowledge as to whether any brewers had adopted the recommendations of the committee, but he should fancy that beyond exercising generally more care the brewers were largely awaiting the result of the present Royal Commission. He thought that the brewers were exceedingly anxious to have guidance upon the matter. He was satisfied that they were on their guard against arsenic and that there was absolutely no danger lurking on the side of brewing sugar. A scare like this made it quite impossible in an industry of this kind that such a blunder should be made again. He took a different view about the malting, because they could not test their malt as they could test their sulphuric acid, and therefore malting would be rendered safe, first by better methods—perhaps the American method, whereby the fumes did not come directly on the malt—or by better tests, or by selection of fuel. With regard to that he thought that the brewers were likely to have held their hands and waited until this Royal Commission authoritatively laid down the precautions which they ought to take. There was a recommendation in the report of the committee that brewers should require a written guarantee of freedom from arsenic in all brewing materials. He did not think that such a guarantee would indemnify the brewer: the real good of it was that it dinned the word "arsenic" into the ears of the person who was selling brewing materials. It was a sense of too much security which was the source of danger and if in connexion with the selling of brewing materials there was a guarantee pointing to arsenic, people would always be on their guard against it. Nothing was easier than to keep it out; the danger was of forgetting, and the real advantage of this guarantee would be that it would be impossible for persons producing brewing materials ever to forget the risk of arsenic. He was of opinion that the recommendations of the committee in this connexion would be greatly strengthened if official tests for brewing materials were prescribed. If the Board of Inland Revenue could get a test which was practical, easy of application, and gave a substantial security, he thought that it would be of the greatest service. He did not think that an absolute test which was difficult of application would be nearly so useful as a practically sufficient test which could be certain and easily applied. He thought that the danger of rejection was such that the existence of a practical and easily applied, and therefore frequently applied, test would make the maltsters adopt methods which would keep malt perfectly free from arsenic. They would not run the risk of the great loss, both in reputation and pocket, of rejection, and he thought that the frequency of the application and its readiness would be very much more serviceable than what they might call a scientific infallibility. There was no evidence before the committee of any beer which produced evil effects otherwise than by frequent drinking—the toxic character of the beer never rose to such a point that once drunk it produced an evil result. He thought that the proposed test should be made in connexion with the Sale of Food and Drugs Act. The most important thing would be that this Commission, by appealing to the Board of Inland Revenue or some other high authority, should state what it thought was adequate and practicable in the way of watchfulness on the part of the producers; then the ordinary powers of public analysts under the existing statutes would enable them to test beer or brewing materials. It was important that people should know what they had to live up to. In the present state of things there was much costly and difficult litigation, whereas if purity meant to live up to a certain standard decided in a particular way much of this litigation would be avoided and the results to the public would be admirable. He was aware that the committee recommended an official board of referees for this purpose. He was not very fond, if he might use the phrase, of courts *ad hoc*. It was difficult to get good courts. They had good courts in the judicial system and so far as the decision went he should prefer to leave it to the existing courts, but the definition of purity should be a practical one. He did not think that it ought to be made a statutory duty to require a warranty. He did not think that that was any good. He thought that it would be enough to say that it would be an act of great carelessness for a brewer to buy without it. If they were going to say that it was a statutory duty then there arose a great many questions as to what came within the meaning of the word "warranty," but if they put it that a man with a proper conception of his responsibilities would not, in the opinion of this Royal Commission, act otherwise it would have a far more wide-reaching effect. Supposing a man did not do it he would know that if any trouble came he had neglected to do it at his peril and that would have a really wider effect and at the same time it would be less onerous and technical than if it were embodied in legislation and made a statutory duty. He thought that the greatest kindness that this Commission could do the public, especially to the trade, was stating what it thought was the duty of a person, where were his responsibilities and stating in detail how in its opinion he could adequately discharge that duty.

By Sir **WILLIAM S. CHURCH**: With regard to the large discrepancy between the comparative numbers of cases of so-called alcoholic neuritis in the Manchester and Liverpool district and in London or in Scotland he remembered that in its investigations the committee found that the southern malts were much freer from arsenic that the northern, and that might be an important consideration.

By Dr. **WHITELEGGE**: He would have a standard for testing both the finished beer and brewing materials. This would be valuable not only for the purposes of the Inland Revenue but also for the purposes of the Sale of Food and Drugs Act. He thought that the Commission should state that samples should answer such-and-such a test and if they went beyond it they would come within the Sale of Food and Drugs Act. The test should apply to the manufacturer who sold wholesale and not to the actual consumer.

By Professor **THORPE**: The tests which he had in his mind ought to be capable of application by the maltster or the brewer. No doubt more stringent tests would require to be formulated for subsequent use but there should first be such tests as could be applied by practical men engaged in malting and brewing.

EVIDENCE BY MR. GORDON SALAMON.

Mr. **GORDON SALAMON**, chemist and member of the committee of experts, was also examined. In the course of his evidence he said that in the light of present information the line should be drawn higher than one-fiftieth of a grain of arsenic per gallon. In his opinion there was no reason why beer should contain one-hundredth of a grain per gallon. Cases had occurred where it had contained more but they were very rare. Witness discussed at great length the question of tests. In this matter he said that it was necessary to cater for the small brewer rather than for the large brewer who kept his chemist upon the premises or engaged a professional analyst. In the future the large brewer would do as he was doing at present, take *every possible precaution to prevent his product from being contaminated* with arsenic, but the small brewer who had to compete with him would be tempted by cheap material which was possibly impure. He knew that much of the bad malt which was made with gas-coke was offered to large brewers and refused by them because of its containing more arsenic than was now considered desirable and that it had been taken by smaller brewers because of its cheaper price. He suggested that the Commission ought to approve a test which would enable the small maltster or brewer to be sure that what he was sending out was free from arsenic and he thought that the proper application of the Reinsch test would enable him to do so. Witness exhibited to the Commission a specimen of this test disclosing $\frac{1}{100}$th of a grain of arsenious acid per pound of malt. It was, he said, easy of application and would suffice to put the maltster on the *qui vive* He, of course, did not suggest it as an official test but merely for the practical purposes of the manufacturer. He was strongly of opinion that the use of gas-coke as fuel in drying malt should be prohibited. His experience had convinced him that there was no necessity for its use. It was employed simply on the ground of economy, and now that it had been established as a source of danger it should be prohibited. During the past six months the presence of arsenic in malt, even in minute quantities, had become very much rarer, and this he attributed to the diminished use of gas-coke.

The Commission then adjourned.

Wolverhampton and Staffordshire General Hospital.—House Physician, also House Surgeon. Salary (in each case) £100 per annum, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

Burrows.—On May 9th, at The Haven, Harrow-on-the-Hill, the wife of Harold Burrows, M.B. Lond., of a son.

Martin.—On Jan. 21st, at Wellington, N.Z., the wife of Albert Martin, M.D. Durh., of a son.

Permewan.—On May 9th, at Normanton-avenue, Liverpool, the wife of William Permewan, M.D. Lond., F.R.C.S., of a daughter.

Pembrey.—On May 5th, at Parkside, Clewer-green, Windsor, the wife of M. S. Pembrey, M.D. Oxford, of a son.

Rutherfurd.—On the 13th inst., at 12, Newton-place, Glasgow, the wife of Henry Rutherfurd, M.B., a son.

MARRIAGE.

Bryett—Leonard.—On the 29th of April, at Holy Trinity Church, Winchester, by the Rev. Allan Gunn, rector, assisted by the Rev. J. F. Matthews Duncan, M.A., William Robert Bryett, B.A., M.D., London, second son of Lewis Bryett, to Mary Elizabeth, daughter of his Honour the late Judge Leonard of Kerrfield, Winchester, and Queen's Fort, Tuam, Ireland.

DEATHS.

Bodington.—On Thursday, May 8th, at Hotel d'Jena, Paris, George Fowler Bodington, M.D. Durh., aged 73.

Freeland.—On April 15th, 1902, at Parham, Antigua, West Indies, Freeland John Freeland, M.D., L.R.C.P. Lond., M.R.C.S. Eng., L.S.A. Lond., elder son of J. B. Freeland, M.R.C.S. Eng., and brother of Douglas L. Freeland, L.R.C.P. Lond., M.R.C.S. Eng., of Snodland, Kent, aged 40 years.

Hoadley.—On March 14th, 1902, at Havelock, Marlborough, N.Z., Robert Hoadley, M.D., M.R.C.S.E., formerly of Fulham, S.W.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Short Comments, and Answers to Correspondents.

IS IT THE DUTY OF THE PUBLIC VACCINATOR TO VACCINATE ALL APPLICANTS?

To the Editors of The Lancet.

Sirs,—I should be obliged if you would give me your opinion and also, perhaps, elicit that of the public vaccinators as to whether *they are required to vaccinate all who ask, to vaccinate or revaccinate* them with official lymph in their public capacity—i.e. (because they are the public vaccinators), the patient believing "efficient and innocuous lymph could only be obtained by them"? This question is causing concern and unrest in the minds of medical men, controversy and heated argument on the part of the public, especially at different boards of guardians when large medical bills are presented by their clerk for payment. Such was the case at the last meeting of the Guardians of Poole Union when a bill of £169 for revaccination was produced by our clerk. The chairman of the Relief Committee proposed, "That a list of all those who had availed themselves of revaccination by the public vaccinator (not being paupers) at the expense of the ratepayers should be published." I seconded this, observing that I thought it mean and contemptible to resort to the public vaccinator as many well-to-do people had done for themselves, their families, and household, and that it was a reflection on, and insult to, their private medical man to assume, or to think for one moment that only by vaccination by the public vaccinator could they be efficiently secured from *the risk of contracting small-pox. This caused a fellow guardian who was sitting next to me at once to rise and, with some warmth, to state that* he dissented entirely from my speech, for he had availed himself of the public vaccinator because he was told, and it had been stated in Parliament, that efficient lymph could only be obtained from the public vaccinator; he had been revaccinated since infancy four times and without result until he was vaccinated recently by our public vaccinator; he deprecated the suggestion that men of means and position could do so from unworthy motives; "he offered the fee," which was refused; and he considered as a large ratepayer, and even for example' sake, he was perfectly at liberty to avail himself of a public duty which, in his opinion, could only be done efficiently by the public vaccinator. I replied that although in the case of the last speaker all who knew him as we did could not for a moment have thought that he had been vaccinated or had had his servants vaccinated to avoid the paltry fee, for we well knew his open-handed generosity and large-heartedness, still many had done so presumably for that reason, and I did protest against the statement that efficient lymph was to be obtained only by the public vaccinator, and that if it were so—that we could not be vaccinated successfully without evil consequences only by accepting of vaccination by the public vaccinator—it would indeed be sad and lamentable and must be quickly rectified, but I thought that I could prove that this was not so, that it was not necessary to receive pauper medical aid in order to be protected effectually by the great blessing of vaccination. I had myself lately revaccinated with most excellent results my two daughters, my son, one of my servants, and a friend with excellent lymph obtained from the Jenner Institute. I have also procured excellent lymph from Dr. Renner, Marylebone-road, N.W. I thought the public vaccinator should have accepted the fee offered and not have included our fellow guardian in his list for payment by the guardians, at any rate this was my custom when I was in my early years, for a short time, a public vaccinator.

Your reply, I think, will interest many readers of The Lancet and oblige,

Yours truly,

May 12th, 1892. Frederick H. Alderson, M.D. St. And.

⁂ A public vaccinator must perform his duty towards anyone who claims his official services, but a good citizen would not desire to make his neighbours pay unfairly for him. A leading article in this week's issue deals with other points in Dr. Alderson's letter.—Ed. L.

"FALSE COLOURS."

To the Editors of The Lancet.

Sirs,—My attention has been drawn to an editorial note in The Lancet of May 10th, p. 1369, having reference to myself. As I have always found that your journal is conducted with courtesy as well as ability I am the more surprised that you should not have communicated with me before *inserting it.* You would then have learnt privately the facts to which I request you to give the same publicity as the paragraph in question.

1. I have never authorised any person to represent me as a medical member of the Malthusian League. 2. I have never been aware directly or indirectly that I was so represented. 3. I do not, as you unjustly assume, receive the *Malthusian* monthly, but, on the contrary, have never even seen or heard of the paper for at least nine years. 4. I am not, and never have been, a subscribing member of the League and have no knowledge or information of having been made an honorary member, although to some extent the needs of modern civilisation compel me reluctantly to assent to its general principles. I may add *that I am no more responsible for the manner in which I am described* without my knowledge in a medical direction than I am for the fact that I receive many letters addressed me as "the Rev." because I am an M.A.—not, I am sure, for any other qualification. In conclusion, I may say it would be extremely inconsistent with my published and repeatedly expressed views regarding the training and government of the medical profession in this country to cause myself to be considered a member of that body. This I say in no personal disrespect to medical men, among whom I reckon some of my warmest friends but in honest disavowal of the suggestion that your paragraph would seem to convey.

I am, Sirs, yours faithfully,

H. S. Schultess Young.

Essex-court, Temple, E.C., May 12th, 1902.

THE TREATMENT OF STAMMERING.

To the Editors of The Lancet.

Sirs,—Can any of your readers kindly give me hints as to the best way of dealing with a case of stammering in a young lady, aged about 18 years? I imagine that it may be necessary to put the patient under the care of someone trained in the teaching of elocution and voice-production. If so I shall be grateful to any brother practitioner who can privately recommend me a teacher whom he has found to be efficient and satisfactory. I inclose my card and, venturing to trespass on your kindness, ask you to be so good as to permit me to call at your offices for any replies to my query.

I am, Sirs, yours faithfully,

Koax-Koax.

THE INSURANCE VALUE OF THE LIFE OF A MEDICAL MAN.

Dr. J. Howe Adams of Philadelphia, writing in an American contemporary on the subject of accident insurance, makes some interesting remarks with regard to medical men as "risks." He says:—

> "The two classes which are considered the cream of the accident business are the '*preferred*' and the 'select' who need pay only *$5 and $4 respectively a thousand, the difference being that the* select is allowed twice the maximum amount of the preferred for death as a rule. Accident companies regard the physician as a better risk than the surgeon and they regard the city physician better than his brother practitioner in the country. As the city physician is regarded as the best risk he is put in the best class, the select. Next comes the physician and surgeon with city practice only; he is placed in the preferred class, while the country physician and surgeon is placed down in the classification as 'ordinary,' which is the fourth from the top, for which he must pay twice as much as his city brother and be limited to half the amount of indemnity in case of accident or death by accident. This is the cold blooded view which the accident companies take of the dangers of the country doctor's life."

FOREIGN MEDICAL LITERATURE.

To the Editors of The Lancet.

Sirs,—*Concerning* foreign literature, I beg to inform "Northern Reader" (The Lancet, May 3rd, 1902, p. 1293) that the leading medical booksellers of Berlin are Messrs. Speyer and Peters, N.W., 43, Unter den Linden; Urban and Schwarzenberg, N.W., 39, Dorotheenstrasse; and A. W. Hirschwald, N.W., 68, Unter den Linden. The leading medical weekly periodicals are *Deutsche Medicinische Wochenschrift*, *Berliner Klinische Wochenschrift*, and *Münchener Medicinische Wochenschrift.*

I am, Sirs, yours faithfully,

Berlin, May 7th, 1902. Dr. Eugen Cohn.

"POISONOUS PROPRIETARY MEDICINES."

To the Editors of The Lancet.

Sirs,—I have just noticed your remarks in reference to the sale of "Bromidia," in your paper of May 3rd, by "a Fleet-street Druggist." Being the "Fleet-street Druggist" referred to, I beg the favour of the insertion in your next issue of the following. Quoting your own motto, *Audi alteram partem*, you say I have been in the habit of selling "Bromidia" to anyone who might ask for it. That is not correct. I have been in the habit of dispensing it, but not otherwise selling it. That particular bottle was *the first sold* entire over the counter. And further on you state that I was in the habit of selling it without labeling it "Poison." (Though that would be true if we were in the habit of selling it.) We only label dispensed medicine according to the instructions of the doctor. As regards labelling the bottle "Poison," let me remind you that that is not our duty. It is the duty of the maker and first vendor. We are not supposed to know the composition of a "patent medicine," and it would be the height of impertinence to put "Poison" upon another's preparation which the maker does not acknowledge as a "poison" and moreover calls it by some innocent name.

You make the following remarks to the jury's rider: "How long are such representations by juries to be made and to go unheeded? How often are lives to be sacrificed before the law regulating the sale of poisonous proprietary remedies is amended?" In this particular instance, and in some others, the medical profession are alone to blame, if blame exists. If medical men would but trust "druggists" to dispense their prescriptions very little would be heard of such sad accidents. The fact is, many medical men when they leave *the hospital* are not able to write a prescription. Hence they have recourse to these quack compounds. The patient soon discerns the preparation and purchases for himself. "Druggists are not trusted to dispense a simple pill of quinine or iron, and many other single remedies and compounds, too, but the doctor must go to America, France, or Germany for the preparation he wishes to administer to his British patients.

If all intended for the medical profession were compelled to work for nine months behind a "druggist's" counter, where a good dispensing business is done, they would not only know how to write a prescription but be able to dispense it. As things are, with their insufficient knowledge of pharmacy they find it easier to prescribe a nostrum. The bottles of "Bromidia" are not labeled "poison" and do not state the use or the composition. Who would suppose that under the name of "Bromidia" it was a preparation of Indian hemp and in addition every dose of it contains a poisonous quantity of chloral? After the fatal accident I found a formula in "Harwood Lescher's Recent Materia Medica" and one in Martindale's, also one in a trade journal, all three differing from one another. These I gave to the coroner who read two of them to the jury. He evidently thought it quite natural that one might not know the contents till after an accident.

I am, Sirs, yours faithfully,
Fleet-street, E.C., May 13th, 1902. GEO. P. POND.

⁂ We do not understand every word of this letter. Mr. Pond will acknowledge that it is unfortunate that the only bottle of "Bromidia" ever "sold entire over the counter" should have brought about a tragedy. We endorse his regrets that medical men nowadays should be too often inexpert pharmacists.—ED. L.

THE "Y" FUND.

SURGEON-GENERAL H. S. MUIR begs thankfully to acknowledge additional donations towards the above Fund from Lieutenant-Colonel Sir John G. Rogers, K.C.M.G., D.S.O., A.M.S. (retired); Surgeon-Lieutenant-Colonel Sir J. R. A. and Lady Clark; Lieutenant-Colonel J. J. Lamprey, I.M.S. (retired); Professor D. J. Cunningham; Dr. Murison; Dr. J. R. S. Robertson (Southsea); Dr. E. L. Fenn; Dr. Blandford; Dr. Frazer; Mrs. Snape; Mr. and Mrs. H. Gilbert Barling; Surgeon-General and Mrs. I. O'Farrell; and the following officers and ladies of the Royal Army Medical Corps:—Colonel and Mrs. W. J. Charlton, Colonel and Mrs. W. F. Stevenson, Lieutenant-Colonel and Mrs. W. L. Chester, Lieutenant-Colonel and Mrs. W. E. Webb, Lieutenant-Colonel and Mrs. H. K. Allport, Lieutenant-Colonel and Mrs. T. B. A. Tuckey, Lieutenant-Colonel and Mrs. C. B. Hill, Lieutenant-Colonel and Mrs. L. W. Swabey, Lieutenant-Colonel and Mrs. Dick, Major and Mrs. H. Lynden Bell, Major and Mrs. F. H. Treherne, Major and Mrs. D. V. O'Connell, Major and Mrs. A. Kennedy, Major and Mrs. T. H. F. Clarkson, and Major and Mrs. H. M. Sloggett; Colonels J. L. Notter, W. J. Fawcett, J. P. Rooney, and G. D. N. Leake; Lieutenant-Colonels C. A. Webb, D. F. Franklin, W. Rowney, James, J. F. Brodie, M. Dundon, J. Stevenson (retired), Grant, Alexander, C. A. P. Mitchell, U. J. Bourke, F. T. Wilkinson, and T. M. Corker; Majors A. Stables, J. W. Jérome, M. T. Yarr, A. Dodd, C. W. Allport, G. H. Barefoot, W Hallaran, G. F. Alexander, A. J. Luther, A. de C. Scanlan, S. G. Allen, G. J. A. Tuke, J. D. T. Reckitt, H. A. Cummins, C.M.G., and J. Hickman; and Captains Hardy, E. McK. Williams, G. S. McLoughlin, D.S.O., A. Pearse, J. Grech, G. S. Mansfield, and C. T. Samman. The fund now amounts to £140. It may be explained that this is in response to an appeal made privately to members of the profession for benevolent aid in a distressing case which has been described in a letter sent to a limited number of medical men (who would help the cause by kindly "handing on" to *confrères*). Should any reader of THE LANCET desire further particulars with a view to expressing *practical sympathy*, a copy of the letter will be forwarded on application to Surgeon-General Muir, 26, Kensington-gardens-terrace, Hyde Park, London, W.

PROPOSED MEMORIAL TO THE LATE SURGEON-GENERAL W. NASH, A.M.S.

THE following additional subscriptions to this fund have been received:—

	£	*s.*	*d.*		£	*s.*	*d.*
Lieutenant-Colonel H. Grier, R A.M.C	1	1	0	Colonel J. F. Supple, C.B., R.A.M.C.	1	0	0
Lieutenant-Colonel R. H. Forman, R.A.M.C.	0	10	0	Colonel W. Allan May, R.A.M.C.	0	10	0
Lieutenant-Colonel G. Hughes, D.S.O., R.A.M.C.	1	1	0	Previously acknowledged in THE LANCET	81	6	6
Major D. Semple, R.A.M.C.	1	1	0	Total	£86	9	6

HER 167TH APPEARANCE.

WOMAN named Susan Wilson appeared at the Salford Police court recently on a charge of drunkenness. She is a familiar acquaintance of the magistrates and the police, having been before the court 167 times. On a Saturday evening she requested the police at the Town Hall to take her into custody. She liked the workhouse better than the prison but she said it was too late to g there on Saturday night. She was discharged in order that she might go to the workhouse. But of what use is this constant round of ginshop, workhouse, police, and prison? If in a home she might be saved from herself. Familiarity, no doubt, blunts the sense of shame and the report of the case seems to show that the humorous rather than the pitiful aspect of the case presented itself to the court on her 167th appearance.

THE INHABITED HOUSE DUTY.

To the Editors of THE LANCET.

SIRS,—Will you allow me to call the attention of medical M.P.'s and Parliamentary Committees to the serious injustice under which medical men lie with regard to their assessment of house tax? A medical man cannot live where he likes, he has to choose his house both as regards size and position from a purely business point of view. To all intents and purposes the medical man's house is a house of business. Why is not the house rated as such? Medical men (and schoolmasters who are in a similar position) are called upon to pay 100 per cent. higher house tax than a tradesman in the same locality. This high rating is a direct tax upon their industry. This is not a small matter to men whose expectation of life is less than that of any other calling bar publicans and sinners, and therefore whose productive period is of the shortest and most precarious. If the attention of the Chancellor of the Exchequer was called to this fiscal anomaly I am sure tardy justice would at last be done.

I am, Sirs, yours faithfully,
Ilkley, May 11th, 1902. A. H. BAMPTON.

THE R.A.M.C. UNIFORM.

To the Editors of THE LANCET.

SIRS,—May I point out to your correspondent, "Surgeon-Captain," in THE LANCET of May 10th, p. 1370, that the Sam Browne belt has *not* been officially ordered for Volunteer medical officers, and it is, I believe, not the intention of the authorities that it should be worn by medical officers of units? Unfortunately a volunteer association, although unauthorised, stated that the Sam Browne belt was required except in review order.

I am, Sirs, yours faithfully,
May 10th, 1902. V. M. O.

◆

A Vain Woman is strongly recommended to have nothing to do with the quacks in question. Plastic operations in surgery should, in our opinion, only be performed to remedy grave defects—conditions which make the victim an object of repulsion. The signs of ordinary wear and tear of life should not be made the subject of surgical interference, and no self-respecting surgeon would operate upon a patient for the gratification of the patient's vanity solely. Secondly, such a plastic operation as "A Vain Woman" seeks information about would probably be unsuccessful from the first; it might be attended with dangerous complications; and, at the best, it would only be of the slightest temporary benefit to her appearance.

G. F. S.—We are not prepared to say that any one text-book on the subject is better than any other. We have reviewed several favourably. Our correspondent might attend the classes at the Sanitary Institute, Margaret-street, London, W., when his lecturers would advise him which text-books they would prefer him to use.

Yenikeny.—If our correspondent advertises his wants in the usual manner he will find out the market price. Such matters are only decided by mutual arrangement.

A. J. N.—The Drouet Institute are a set of quacks.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.) West London (2.30 P.M.), London Throat (2 P.M.), Royal Free (2 P.M.).

TUESDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

WEDNESDAY (21st).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.).

THURSDAY (22nd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

FRIDAY (23rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.). West London (2.30 P.M.), London

Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square, (9.30 A.M.), City Orthopædic (3.30 P.M.).

SATURDAY (24th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.), Throat, Golden-square (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (20th).—PATHOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Annual General Meeting. Election of Officers. Ordinary Meeting. Dr. Hunter: Infective Lesions of the Tongue, Stomach, and Intestines in Addison's Anæmia (Lantern Demonstration).—Dr. Rolleston: Membranous Cholangitis.—Mr. A. Lucas: Unusual Variety of Knee Joint in Hæmophilia and Congenital Atresia of the Small Intestine.—Dr. F. J. Smith: Disseminated Carcinoma Simulating Tubercle.—Dr. Pennell: Sarcoma of the Suprarenal Body.

WEDNESDAY (21st).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—7.30 P.M. Mr. D. J. Scourfield: Exhibition of Fresh-water Entomostraca.

ROYAL METEOROLOGICAL SOCIETY (Society's Rooms, 70, Victoria-street, S.W.).—4.30 P.M. Papers:—Mr. W. H. Dines: Report on the Wind Force Experiments on H.M.S. *Worcester* and at Stoneness Lighthouse.—Dr. H. R. Mill: The Cornish Dust Fall of January, 1902.

UNIVERSITY COLLEGE MEDICAL SOCIETY (Gower-street, W.C.).—8.30 P.M. Address: Prof. J. Rose Bradford: The Relation of Biology to Medicine.

THURSDAY (22nd).—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8.30 P.M. Clinical Evening. Cases will be shown by Mr. W. Watson Cheyne, Dr. A. Whitfield, Dr. A. Morison, Mr. F. Jaffrey, and others.

NEUROLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Clinical Evening. Cases will be shown by Mr. R. Cross, Dr. F. Weber, Dr. F. Buzzard, Dr. Colman, and others. (Patients at 8 P.M.)

FRIDAY (23rd).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Annual General Meeting. Election of Officers for Session 1902-1903. Papers:—Sir T. Barlow, Bart., and Dr. H. B. Shaw: Inheritance of Recurrent Attacks of Jaundice and of Abdominal Crises with Hepato-spleno-megaly. (Two cases will be shown.)—Dr. W. Hale White and Mr. C. H. *Golding-Bird*: On the Subsequent History of Three Cases of Colitis in which Right Lumbar Colotomy was performed several years ago.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

TUESDAY (20th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. W. Ewart: Clinique. (Medical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Taylor: Heart Murmurs, their Significance and Treatment.

POST-GRADUATE CLINICAL DEMONSTRATION (Westminster Hospital).—4.30 P.M. Mr. W. Turner: Surgical Cases.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Mr. Ballance: Cerebral Abscess.

WEDNESDAY (21st).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Cantlie: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Eccles: Surgical Anatomy.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. T. H. Green: Difficulties in the Recognition of Pulmonary Tuberculosis. (Opening Lecture of the Summer Session.)

THURSDAY (22nd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Baldwin: Treatment of Injuries.

CHARING-CROSS HOSPITAL.—4 P.M. Dr. J. Mitchell Bruce: Medical Cases. (Post-Graduate Course.)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Penrose: Demonstration of Selected Cases.

FRIDAY (23rd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. D. Grant: Clinique. (Ear.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Abraham: Cases of Disease of the Skin. (Prof. Unna of Hamburg is expected to give the Demonstration.)

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only. AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières Paris.

A Lecture

ON

THIRTY YEARS' WAR AGAINST LUNACY.

Delivered before the Post-Graduate Medical Association on Feb 12th, 1902,

By T CLAYE SHAW, B A., M D, F R.C P
Lond,
LECTURER ON PSYCHOLOGICAL MEDICINE AT ST BARTHOLOMEW'S HOSPITAL; LATE MEDICAL SUPERINTENDENT OF THE LONDON COUNTY ASYLUM BANSTEAD

GENTLEMEN,—With your permission I propose to devote this lecture which you have honoured me by coming to hear to a consideration of the changes and progress in the treatment of lunacy during the last 30 years, the period of my active participation in its various manifestations as seen in public institutions.

The two most important events during the time were, I think, the passing of the Metropolitan Asylums Act, 1870 (known as "Gathorne Hardy's Act"), and the transference of the administration of asylums in the year 1889 from the jurisdiction of the magistrates to that of the county councils. As my experience relates solely to asylums in connexion with the metropolis and its districts my remarks will be made chiefly with regard to them.

There is no doubt that prior to 1870 the London asylums of which there were two—viz., Hanwell and Colney Hatch—were far behind most of the asylums in the north of England and in Scotland, as well in architectural arrangement and administration as in decoration and sanitary conditions The non restraint treatment had been fully recognised—and, indeed, at Hanwell, under the auspices of Dr Connolly, it had acquired its most conspicuous development, though, of course, he only professed to put into large practice the principles and treatment of Pinel which were first introduced into this country by Mr Gardiner Hill. At the time that I am speaking of (the late "sixties") there existed a dual superintendence of the asylums, an imperfect recognition of the advisability of vesting the responsibility of the administration of the asylum in the medical superintendent, and a very inadequate conception of the importance of having a large and efficient medical staff The accommodation itself was notoriously inadequate to the requirements of the metropolis and in the workhouses scores of persons of unsound mind were kept in conditions quite unsuitable for them. The medical staff was ridiculously small For the care of 2000 patients there were two medical superintendents and two assistant medical officers, one on each side. Anything like systematic treatment of patients was impossible and case-taking was only a name. There were no laboratories for scientific work and the teaching of the subject was not recognised in the schools The Lunacy Commissioners, however, were very active in their repeated demands for more accommodation and for alterations to bring the asylums in line with the places where the comfort, at any rate, of the patients was studied with success. It was about this time that Dr Maudsley's book on "Mind" was published and it marks an epoch in the history of the literature of insanity in this country I say that it marked a great advance because it introduced to the notice of the specialty the psychological side of the clinical work that was in a certain estimation and it materially helped to correlate the two. The study of psycho-physics although in course of investigation in Germany, had scarcely penetrated to this country and the whole subject was approached merely from the side of the exposition of symptoms without radical efforts being made to bring to bear the study of morbid anatomy and other kindred methods Of course we must not forget that at this time little was known of bacteriology and the methods of staining tissues were, indeed, only just being brought to notice in the general medical schools The irksomeness of an assistant medical officer's life at times was almost unbearable for going out was often impossible and I have known men confined within the walls of the asylum for as long as six weeks at a time in the absence of the chief As to the nursing staff the less that is said of it the better Not that there were not numbers of very intelligent men and women in care of the patients (and there were probably more stability and permanence in the staff of attendants than there is now) but the hospital system had not been in any way introduced and, indeed, the use of the thermometer was in its infancy as regards its application to lunacy Instruction was in no way given to the nursing staff and whilst the pay was poor the hours on duty were long and the accommodation for amusement and for rest was of the barest description. At this time, too, a deal of power was invested in the lay authorities of the asylum and, as might be expected, this led to a certain amount of conflict as to infringement of territorial rights between the strictly professional and the lay element. The patients, however, were kindly treated and in justice I must add that the attendants, from having so much necessarily left in their hands owing to the impossibility of complete medical supervision, became very expert in their acquired interpretation of symptoms and in their personal management of the patients One source of danger, owing to the insufficiency of medical supervision, was that stock bottles of medicines were often kept in the wards and these stock mixtures included sedatives such as digitalis and tartar emetic. I do not say that these sedative mixtures were ever surreptitiously given to the patients by the attendants but there was always present the possibility of it. Post-mortem examinations were sometimes made, sometimes not There was no understood necessity for making an examination in every case where possible and this must have led to many inaccuracies in the table of causes of death as well as to the want to the patients during life of that security from rough treatment which is only engendered in some attendants by the knowledge that an injury inflicted during life may lead to consequences which will surely be brought home after death.

However incomplete and unsatisfactory from our present point of view the then management of asylums was, I wish to state that in its way a great deal of work was done. Everyone from the committee downward did his best according to his lights but it was not until the idea grew and finally became established that asylums should be treated as hospitals and that therefore the medical element was the essence of the system and that the lay element should be subordinated to it, that a wider reaching view of the subject was possible The old system of treating lunatics was so mechanical in kind and was so crudely based that it took time to bring home to people the notion that insanity was a disease to be studied on the same lines as disease in general and if it took some time to convince the profession of this we may easily see that some difficulty was experienced in convincing the lay governing bodies of this truth and in getting them to recognise the expediency of looking at everything connected with the administration of an asylum from a medical point of view It was the publication of the views of Dr J Hughlings Jackson in the Croonian Lectures and elsewhere that probably more than any other work led to the true view of how insanity should be regarded, and I beg to take this opportunity of emphasising the great regard that all students of mental disease have for this eminent physician The theory that insanity is a dissolution and that it must be interpreted according to the laws postulated by Dr Jackson was the means of letting in more light upon the disease than can be conceived by those who have been from the first taught to take that view of it.

It must now be stated that there is a common opinion to-day that, however bad things were at the time I am speaking of (more than 30 years ago), we have not made any material progress in the successful curative treatment of insanity—that, in fact, no more people are now discharged cured from asylums than formerly I am inclined to think that there is a great deal of truth in this It must be remembered that although we know more of the nature and conditions of insanity than we did 25 or 30 years ago we are still in the dark about a great deal and we are still behind other countries in the amount of medical care allotted to this form of disease The general principles of treatment were the necessity of feeding the patient and the value of rest and of occupation with open-air exercise. The medical treatment consisted in the rather extensive use of sedatives to control excitement. And what is the treatment nowadays? Very similar to what it was then, except that in some asylums there is perhaps more opposition to the control of symptoms by sedatives than there was whilst in others the introduction of subcutaneous injections of powerful new alkaloids is very frequently resorted to

Upon the question as to when a patient is fit for discharge a good deal depends upon the personal equation of the physician and upon some other circumstances that are not quite under his control, such as the wishes of the friends to take the patient out, &c. In America the percentage of cures to admissions is not so great as it is in this country because they are much more particular over there before they allow anyone to leave as "cured." They also have fewer readmitted as "relapsed" cases. In consequence of the great difference that holds in men's minds as to when a patient should be discharged as "cured" I do not think it advisable to quote statistics and I may for the present dismiss this portion of the subject with the remark that in most particulars asylum statistics are unreliable and therefore useless. If, however, the percentage of discharges was about the same as now, showing that there has been no great advance in direct curative treatment, there is little doubt that the percentage of "accidents" was greater and I think that the patients were noisier and more difficult to manage. This I attribute partly to the fact (which I do not attempt to explain) that we had at that time more violent and maniacal cases than we seem to get now, but especially to the fact that the patients were allowed beer (of which some of them managed to obtain a considerable quantity) and that stimulants were generally given to a much larger extent than they now are. Not only have the patients benefited by the curtailment of stimulants but I think that by stopping the use of stimulants by the attendants these are able to treat the patients with more endurance and less irritability. It has often struck me that the amount of apoplexy among asylum patients is very small considering the vast amount of arterial degeneration that one finds, and this I attribute to the low vascular tension from regulated diet, absence of stimulants, and long hours in the recumbent position at night. The proportion per cent. of deaths was larger than it is nowadays and this can be attributed partly to the numbers allotted for treatment to one medical man, making it quite impossible to give more than a cursory daily examination even to the acute cases, but chiefly to the great improvements that have been introduced in the general hygienic conditions of the existing buildings, such as improvement of ventilation, warming of single rooms and dormitories, better laundry arrangements, &c. Patients with phthisis were allowed to intermingle freely with others, but syphilis was well recognised as a cause, though perhaps not to the full extent that it now is, and the curability of myxœdematous insanity by thyroid extracts was quite unknown. Though restraint was to some extent practised by means of sleeve jackets I do not think that there was a large or unnecessary amount of it, and seclusion—i.e., the forcible isolation of patients in single rooms—was probably about as common as it is at the present time, though the instructions of the Lunacy Commissioners about it were rather more stringent than they now are.

I pass now to the consideration of the changes brought about by the passing of Gathorne Hardy's Act in 1870 by which the Metropolitan Asylums Board was constituted, a body to which among other things was entrusted the care of "imbecile" patients. Under their auspices two asylums were built at Leavesden and Caterham and afterwards a third at Darenth, and these institutions were nominally intended to hold, and care for, imbecile or feeble-minded people and the quiet senile dements who were detained in the workhouses. It was largely through the advocacy of the late Mr. Ernest Hart that these changes came about. Now I say that these new buildings were "intended" for the imbecile and feeble-minded from the workhouses, but what was the fact? I know because I superintended the opening of the Leavesden Asylum. It is quite true that scores of patients were received from the workhouses, but many were transferred from the county asylums. As the workhouses were emptied of patients the accommodation there was done away with and so a great stress was laid upon the county asylums to take in the cases for which there was now no room in the workhouses and this led to the erection of another asylum for 2000 patients by the Middlesex magistrates. Note this curious fact, that the patients in the Metropolitan Asylums Board asylums were admitted under a special form of certificate (as, indeed, they are now) very different in its text and exactions from the regular lunacy certificates and that all the patients who were transferred from the asylums lost thereby the special form of protection of the Lunacy Acts under which they were admitted to the asylums and came again to be considered as inmates of a workhouse, for these metropolitan asylums are virtually workhouses within the meaning of the Act. Though nominally built for "imbeciles" there were, in truth, very few real imbeciles in them; most of the patients were the offscourings of the chronic wards of the asylums and at times these were very troublesome and noisy, quite unsuitable to the primitive and simple type of construction of these large buildings, with their large wards meant to hold 180 patients each and a limited amount of infirmary accommodation, with little provision in the way of single rooms for noisy or troublesome persons or (as often occurred) for patients who had recurrent attacks of a maniacal or suicidal nature. At first children were mixed with adult patients in the wards, but this evil was counteracted by the building of the Darenth asylum and removing the idiot and imbecile children there from the older metropolitan asylums and from the county asylums.

Owing to the removal of so many patients from the county asylums the vacancies were filled up by the patients left in the workhouses and by the transfer from the private asylums of many strictly county patients who had been boarded-out in them because there was no room for them in the county asylums proper. It was soon found that many of these transfers from the private asylums had recovered and they were accordingly discharged soon after their admission into the county asylums.[1] It is to be noted that the change from the rigorous lunacy certificates of the county asylums to the simpler certificates of the imbecile asylums did the patients no harm at all and this seems to show that for many of the patients who are now in the county asylums the present form of certificate is needlessly strong. There is no doubt that scores of the patients who are now in the county asylums might be placed in the metropolitan asylums if room existed for them, but then the difficulty remains that the accommodation in the existing county asylums would not be able to absorb all the acute cases in the workhouses and many in the outlying county asylums who are boarded-out because there is not at present room of the proper kind for them in the existing asylums which can accommodate only a certain amount of disease of the acute or turbulent variety. As it is, only the quietest and most elementary forms of lunacy can be received and treated in the metropolitan asylums because of the large wards and the small amount of hospital accommodation, whilst the number of attendants employed is too small to deal with any but the most inexacting and harmless cases. Naturally the number of "cures" in these asylums is very small; there should not, indeed, be any cures, but it would appear that occasionally a curable case slips in by accident or someone is transferred whose symptoms have not been properly reckoned with. It would appear that these large workhouse asylums have reached their limit, for there does not appear to be any inclination to extend them. What they have demonstrated, however, is that a certain class of building can be cheaply erected and maintained in which a large number of patients can be treated, or rather cared for, with success, and that persons who were formerly under very strict legal *régime* can be dealt with quite easily and safely under less elaborate legal safeguards.

At these asylums (Leavesden and Caterham) the experiment was first tried of having one medical superintendent only in care of the whole institution and the result was in all ways successful; it was more economical and it lessened friction, at the same time the working of the two sides was better in the interests of everybody. That the work was arduous and trying will be seen when I say that to look after 2000 patients there were myself and one assistant. I took one side in the morning and he took the other, changing over in the evening. There was no dispenser or clerk for the ordinary clerical work and we had to look after the case-books and conduct the correspondence. I have personally, and alone, admitted as many as 80 patients in one day. Under such conditions medical treatment could not be much more than a name.

About this time (1870) I succeeded Dr. (afterwards Sir Richard) Thorne at St. Bartholomew's Hospital in giving a voluntary course of lectures on insanity. The attendances were small, sometimes 12, sometimes five or six, but a year or two afterwards more interest was aroused and the attendance rose to 20—all voluntary students.

---

[1] This accounts for the large list of discharges from some of the asylums in their early years.

contained a scale of charges for examinations of pathological specimens. In the past year 150 clinical investigations had been carried out. The museum was open all day to members and was much resorted to for private study. The following institutions were open to the members for clinical work: the Evelina Hospital for Children, the Dreadnought Hospital, Greenwich, the North-West London Hospital, the Hospital for Diseases of the Throat, Golden-square, the Westminster Ophthalmic Hospital, the North London Hospital for Consumption, the Blackfriars Hospital for Diseases of the Skin, the East London Hospital for Children, and the Victoria and Albert Docks Hospital. The report concluded with the expression of the hope on the part of the council that the results obtained justified the support of the institution by all members of the profession.

Sir **WILLIAM BROADBENT**, in moving the adoption of the report and the balance-sheet, said that they were entitled to support from the public. Personally he regretted that they were so dependent, but their income did not equal their expenditure and they not only had to go to the public to replace capital expenditure but they still had to rely on that support for some part of their annual expenditure.

Mr. **JONATHAN HUTCHINSON** said that large donations had been given to several institutions and he submitted that the Polyclinic had an equal claim to such benefits. They had formed a committee to study cancer and he had not the least hesitation in saying that money could not be devoted to a more charitable purpose and with greater certainty of producing good results than by its being given to the Polyclinic.

Dr. C **THEODORE WILLIAMS** spoke on the financial condition of the college and took a hopeful view of the position of affairs.

Dr. C. O. **HAWTHORNE** drew the attention of the council to the fact that it would be well if members of the council would also make themselves members of the college.

The report and balance-sheet having been duly passed, Dr. **GUTHRIE RANKIN** proposed, and Dr. R. **PURDIE** seconded, the following gentlemen as members for election on the council:—Dr. T. B. Crosby, Mr. D. Dallaway, Mr. Reginald Harrison, Mr. E. Jessop, and Dr. H. Tilley.

A protracted discussion arose as to the right of members to nominate other names for election than those submitted by the council. Finally Mr. C. G. D. **MORIER** proposed, and Dr. L. **WILLIAMS** seconded, the name of Mr. T. J. Hitchins as a candidate for the council.

The following was the result of the ballot for the five vacancies:—Dr. Crosby, 16; Mr. Harrison, 16; Dr. Tilley, 15; Mr. Jessop, 13; Mr. Hitchins, 11; and Mr. Dallaway, 9

A vote of thanks to Sir William Broadbent for presiding was proposed by Mr. **JAMES CANTLIE** and seconded by Mr. **HITCHINS**. This was duly acknowledged and the meeting ended.

THE METROPOLITAN WATER-SUPPLY.

VI.[1]

THE WEST MIDDLESEX WATERWORKS COMPANY.

THE West Middlesex Waterworks were projected at the early years of the last century to supply a part of the West End of London, which was at the time being rapidly "developed," and was without an adequate supply of water. The first Act obtained by the company authorised it to supply Marylebone and certain parishes and places as well as "parts adjacent." The Select Vestry of Marylebone objected to the pavements being taken up for laying the pipes, but in the year 1810 the objection was overcome by the action of Parliament and an Act was passed which increased the authorised area of supply and this rendered impossible any further interference on the part of the vestry. The earliest Acts obtained by the company were 46 Geo. III., c. 119, 50 Geo. III., c. 32, and 53 Geo. III., c. 159, and these were the only Acts obtained by the company before the year 1850.[2] At the middle of the last century the water used by the company was abstracted from the Thames at Barnes and passed into two subsiding reservoirs which covered an area of about 16 acres; these reservoirs were partially supplied also by water which came through the gravelly beds of the district. From the reservoirs the water passed through an iron pipe across the bed of the Thames to the Middlesex side and was pumped to the customers. None of the water was filtered. There were service reservoirs at Kensington and at Barrow-hill, and a supply was given in all cases three times a week "and more frequently in parts of the district where it was required." In July, 1855, water was first supplied from Hampton, where a new station had been erected. At this date the Barnes reservoirs were capable of holding a six days' supply and filter-beds, three in number and having an area of one and a half acres, had been constructed at Barnes. The company then proposed to abandon the service reservoir at Kensington "in order to save the cost of covering it,"[3] for it was situated within the five-mile radius and therefore under the Metropolis Water Act, 1852, it was necessary that it should be covered or abolished. The reservoir at Barrow-hill, Regent's-park was covered and it served to supply the higher parts of the district, the lower parts being supplied directly from the distributing mains. The average quantity of water distributed daily was something between 6,000,000 and 7,000,000 gallons; the number of tenements supplied was 25,732 and the water was furnished "to all parts of the district daily, Sundays excepted, and in some parts twice a day."[4]

The authorised area of supply possessed by the West Middlesex Company is a very large one and includes Barnes, Battersea, Bloomsbury, Brentford, Hanwell, Heston, Kew, Mortlake, the Strand, St. Clement Danes, and St. Paul's Covent Garden. According to the statement presented to Lord Llandaff's Commission which was put in at the fifty-second sitting[5] the districts actually in the County of London supplied are the whole of Willesden, parts of Chelsea, Fulham, Hammersmith, Kensington, Paddington, St. Anne's Soho, St. Marylebone, St. Pancras, St. James Westminster, St. John Hampstead, St. Margaret Westminster; in the county of Middlesex, Acton, Chiswick, Ealing, and Hendon. The companies which supply districts within the authorised area of the West Middlesex Company are the Chelsea, the Grand Junction, the New River, the Lambeth, the Southwark and Vauxhall, and the Colne Valley.[6]

The present arrangements for carrying on the business of the company are briefly as follows. Water is abstracted from the Thames at Hampton, it is pumped to storage and subsidence reservoirs at Barnes and Barn Elms, and filtered at Barnes. It is then conveyed under the Thames to Hammersmith whence it is pumped into the districts supplied, and to service reservoirs situated at Campden-hill (Kensington), Barrow-hill (Regent's-park), and Finchley-road, Willesden. A supply can be sent to another reservoir which is situated at Shoot-up-hill either from Willesden or from Barrow-hill. Of late years many improvements have been made in the works of the company and it happened that the improvements were made at a time when the full statutory dividends of the company had been regularly paid for some years and the back dividends to which the shareholders were entitled had also been fully paid. This, the secretary of the company assured Lord Llandaff, was a coincidence. It was not found necessary to charge any repairs and renewals to revenue account from the year 1879 to the year 1886 (inclusive), but it happened that from 1897 to 1899 three filter-beds were reconstructed at a cost of £21,426,[7] and during every year from 1887 to 1897 a considerable outlay was found to be requisite in improvements—e.g., a new engine, 18 new boilers, office alterations, &c. It would be interesting to know accurately if the plants of the metropolitan water companies which do not pay their full dividends have recently been as thoroughly overhauled as has the plant of the West Middlesex Company.

The most recent improvements and changes which have been effected are shown in Table I., the second column of which gives details of the state of the undertaking in December, 1901, according to the report of the Water Examiner appointed by the Local Government Board.

The subject of insanity was then not recognised in the examinations though the University of London insisted on a knowledge of psychology for the M.D degree—the actual title being *the "senses, the intellect, and the will, including* the theory of moral obligation." Later the colleges recognised the advisability of including questions relating to insanity in the papers and the University of London changed the heading of the subject to "Mental Physiology, especially in Relation to Mental Diseases," and besides pure psychology there was instituted a separate paper on insanity In addition to the lectures clinical instruction was given at the Leavesden Asylum. The example (begun, I believe, at St. Bartholomew's Hospital) was gradually followed at the other schools and there is not now any medical school without its teacher in insanity. The course of lectures was by no means a favourite one at first and only when it was made compulsory was a good attendance secured. The subject was so new, questions of psychology were so out of the groove of reading of the medical student, that there is no wonder that a little gentle compulsion had to be used to get men to take up the subject. Even now the full teaching of psychology and insanity is only partial; it is done at three hospitals—viz., St. Bartholomew's, Guy's, and University College. At the last hospital the teaching is probably the most ideal, for there are a separate psychologist and an independent lecturer on insanity, whilst there is yet a third lecturer there on the important subject of psychophysics. It is rather an anomaly that the teacher of insanity should have to teach psychology—it is like making the lecturer on physiology give the course on medicine, but no doubt the combination of an arts department with the medical department at University College is the cause of the special *professor there. We have recently begun the special and* separate teaching of psycho-physics at St. Bartholomew's Hospital but time is still required for its full development.

We now come to the third division of the subject, the conduct of the asylums under the county councils, which dates from the year 1890. They (the county councils) took an eminently practical view of the subject. They saw at once the necessity of placing one man in charge of the ship and of establishing his position as the responsible head, whilst of course retaining the *ultimate* refereeship in their own hands. This measure at once silenced any question of that internal conflict of authority which was so disastrous not only to the inner harmony of the establishments but to their smooth working At the present moment the medical superintendent is the responsible authority for good or for ill, in pleasant times or in those phases of anxiety to which all people who have to do with an uncertain body like the insane are liable. And by putting the question of a divided superintendentship out of the pale of doubt they consolidated the unity of authority in a way that showed that if lunacy was to be conducted upon scientific, it was also to be done upon business, lines. They then set to work to bring the various asylums in harmony with the most advanced views of the treatment of insanity They authorised the expenditure of what money was required for improving the light, for ventilation, for warming, and for the comfortable decoration of the wards. They introduced the system of centralisation of administration by which each asylum came to be compared with the others and to some extent *regulated* in its conduct by its compeers This system has its merits and also has, perhaps, some disadvantages. It stands on the theory that the conditions of each element of the system are the same, whereas in reality the conditions are rather special in each—e.g., the class of accommodation is by no means the same in one as in another, and so the distribution of acute and chronic cases is of necessity not the same, hence it would not be fair to compare the cost of maintenance in one with what is found adequate in another, and this applies also to the *results*, as given by the statistics, of the various institutions. For a much-subdivided building with small wards more supervision is required and the expense of the staff at one place may be greater than at another merely because of the structural arrangements of the place, but by allowing a certain amount of margin and play in definite directions, necessitated by the special conditions of each unit of the system, and by joining these units into a whole for financial reasons, they are able to present a balance-sheet which is satisfactory to all the individual members; what is in excess in one is counterbalanced by shortage in the other I am not aware that the example of the London County Council has been followed in this respect by other large counties such as Lancashire and Yorkshire, but as the system is still young and is scarcely even yet thoroughly elaborated it may be said to be still on *its trial. No doubt if found to be ultimately successful* it will be copied by those intrusted with the administration of large interests. The important question of nursing or attendance then occupied the attention of the council and striking ameliorations appeared, of benefit both to the attendants and to the patients. The pay was increased and the number of weekly hours of work was lessened, whilst the leave of absence from duty, both weekly and yearly, was materially increased. Of course, all these changes meant additional expense, and of late the cost of maintaining asylums has materially increased This is as it should be It was always a wonder that asylums could be effectively kept up and properly administered for 8s or 9s per head per week and we can only conclude, *cæteris paribus*, that they were imperfectly administered at the lower rates. The treatment of lunacy is an expensive thing and it must continue to augment in expense. The public (i.e., the press) is not satisfied even now that all is being done that should be done for the treatment of insanity and it will not grudge money spent in the investigation of this still obscure disease. After putting its house in order the London County Council proceeded to consider the question of the provision of accommodation for the numbers of new cases in the workhouses and for the housing in their own asylums of the large numbers resident, at great expense, in the outlying county asylums. The question of the proper cost of accommodation to be built was one requiring much care and in this particular steps were taken to regulate the home experience by that of other countries. As a result the *erection of temporary* structures was begun and the results have been satisfactory It has been shown that it is possible to erect in a short time and at a cheap rate structures in which the treatment of acute and chronic cases can be carried on with good results. Naturally, these structures, being temporary, can only be accepted as palliative of the congested conditions that exist, but they suffice until more definite ideas can be launched as to what is the best way of treating the insanity of a place like London.

We must remember that the word "London" means a very *different thing from what it did shortly before* the London County Council came into existence. "London" now means a county which includes tracts of Surrey and Middlesex which formerly had separate asylums of their own, hence the obligations of the Lunacy Board for the County of London have widened by leaps and bounds. Again, London itself is changing very rapidly in its domiciliary conditions and the transfer of habitations to the suburban and country districts is bound to have an effect which it is at present difficult to forecast upon the numbers of the insane who will *in the future have to be treated in the* London asylums proper It is not too much to say that the *idea* upon which asylums should be built and carried on has of recent years found its correct exploitation—viz., that they should be strictly medical in object and carried on in the medical spirit. And so the medical staff has been largely increased, the asylums thrown open for clinical teaching, and encouragement given for the pursuance of medical research by the equipment of laboratories, whilst individual work among the profusion of material that exists for it is encouraged. *A most noteworthy departure was* made by the London County Council in the appointment of a special pathologist who should utilise the material at disposal among the thousands of patients in the asylums and who, equipped with a special laboratory fitted with all modern appliances and methods, should work in the most untrammelled scientific direction upon the great problems of pathology and morbid anatomy that are still before us How well Dr Mott has risen to the exigencies of his appointment is known to all of us Other counties have followed the example and even Scotland *has in this respect* taken a lesson from London.

If it is asked what has been the result of all this change we must reply that to some degree it is already evident in the more comfortable and general sanitary conditions of the patients but that as regard the effects on statistics of cures and deaths we must wait. Great developments are slow often in operation, but we can go on with more confidence when we feel that we are working in the right direction and that we are moving in this way there is no doubt. It is to the young men that we *must look for advancement*, they have the time and the opportunity for work, though it must be confessed that the distractions of asylum life and the somewhat isolated conditions as regards being in immediate touch with scientific surroundings are rather antagonistic to good work. Certainly the superintendents have little time to devote to scientific work, for the numerous calls of the administrative and clerical duties and the necessity of keeping an active look-out over the medical wants and the safety of the patients leave little time for undertaking work that is not strictly concerned with the management of the place.

The latest proposal for dealing with the housing of the insane is the formation of "reception houses" where patients can be detained until it is seen whether it is necessary to send them into an asylum (and, if so, to what kind of asylum) or whether they can be discharged without having to be put away at all. This very excellent proposition of the London County Council has been brought about by the fact that many people now are sent to the asylums who are practically convalescent and have to be discharged at once and partly because cases unfit for the elaborate installations of the asylums have to be admitted and then, being found unsuitable, have to be removed elsewhere at considerable cost and inconvenience. But before these "reception-houses" can be built the Lunacy Act must be altered, and there is reason to think that that will be done as soon as a Bill can be passed. Neither the villa system (so much vaunted in America and Germany) nor the conglomerate system seems nowadays to be the most useful form of building—both have advantages and disadvantages—but the trend seems to be in the erection of hospital blocks (like those at the Wakefield Asylum and at the Lancashire Asylum at Whittingham) where, with all elaborate and modern improvements for treatment and nursing, the acute cases can be placed, leaving the chronics to the larger and less specialised wards. Let it, however, be remembered that many of these "chronics" are the most troublesome of all classes of the insane; they may be incurable, but they are exceedingly troublesome and dangerous and they may tax the energy and resources of the staff in a way that "acute" cases rarely do. Specialisation seems to be now the watchword in providing accommodation and the London County Council has already made arrangements for the home and separate treatment of epileptics and will probably soon provide for the isolation of patients with phthisis, a complication very common in the insane.

I should like to see in London a lunatic hospital for, say, 200 acute cases, equipped with laboratories and all the most recent scientific apparatus, with a complete visiting staff of neurologists and specialists in all important departments. There should be an operating surgeon, a gynæcologist, an electrician, a pathologist, and a dental surgeon, and clinical lectures on insanity and cognate subjects should be given periodically by the staff. There is little doubt that these clinics would be well attended by practitioners and students, and the treatment of the insane would then be at last on a true scientific basis. Such an institution under the control of a public body like the London County Council would have the confidence of the public, and this would be a necessary element, for the cost and maintenance would be exceedingly high, and I think that it ought also to include provision for the treatment of private patients whose friends would doubtless appreciate the opportunities thus offered for specialised treatment. To be sure, there is the difficulty of procuring a site, for the building would have to be in a central part of London, easily accessible to the staff, but this difficulty is not insuperable.

And now I should like to hazard a speculation upon the future treatment of insanity—viz., the introduction of surgery. Some years ago I advocated the employment of surgical methods in general paralysis of the insane. The principle was based upon the relief of pressure which undoubtedly exists. In some of the cases which I reported the symptoms were considerably relieved and I am sure that life was prolonged and carried on under easier conditions. The operations are tedious, though not dangerous, and I hope to see them continued. In Scotland Sir J. Batty Tuke also adopted surgical methods in general paralysis and his results were encouraging. The want of a special operating surgeon in asylums is perhaps the cause why surgery is not more commonly resorted to. When we consider how inaccessible the brain is and look at our present modes of treatment it is little wonder that so many acute cases run into dementia.

Take the case of delusional insanity. It is very probable that often the local lesion is in one of the sense centres from which radiate influences that affect other parts of the brain. The important thing is, if possible, to locate the part of the brain which is primarily affected and then to discuss the probability of relief by operating directly over that region. Surely, a delusion or hallucination is a local sign of the irregular functioning of a certain part of the brain and it is, I contend, within the legitimate methods of treatment to explore that region with the view of relieving local conditions. But how do we act at present? Quite empirically. Of course, we feed the patient and then we prescribe "rest" or "change" and we combat the troublesome symptoms of restlessness or insomnia by sedatives of one sort or another, ringing the changes upon them until we arrive at the one which seems most adapted to the symptoms. And it seems difficult to say what more can be done by this treatment of symptoms than we are doing but let us not forget that our predecessors did as much and that there is no evidence that we are much more successfu than they were. Surely, if a case resists ordinary treatmen and threatens to become chronic, with the superficial lesion that we know exist there can be no reason for not resorting to surgical means which will, at any rate, reveal the actua condition of the brain and point to the advisability o extended treatment in this direction. I believe that just a there are forms of Jacksonian epilepsy which are relieved b operation so there are forms of insanity due to central loca disturbances which may also be benefited in the same way I beg very humbly to put forward this suggestion for th consideration of those who have large opportunities o observation.

I have already referred to the curious fact that number of patients have been taken from the protection of th Lunacy Acts and have done very well under less stringen certificates. There is at present a strong tendency to kee as much as possible—sometimes to a dangerous degree— patients who are undoubtedly insane altogether outside th jurisdiction of these Acts. I refer to the cases chiefly o private patients who are placed either in homes or in th homes of private medical men without any certificate at al This practice appears to be on the increase and the caus seems primarily to be the wish of the friends to avoid th fact that the patient has ever been in a lunatic asylum or hospital. Partly, also, it is due to the somewhat stringen conditions of the lunacy certificates which render the placin a patient in an asylum a somewhat tedious and complicate process, and partly to the reluctance of medical men to sig certificates because of the liability to subsequent trouble an penalties. If the patients who are thus privately housed ca be well taken care of and safely conducted to a cure there much to be said in favour of this modern tendency, but th risks of treatment in this way are certainly great and it pretty sure that the community is not benefited by it. Amon the public to have been "insane" means to have been some time or other in an asylum, and however insan the patient may really have been if she or he has bee treated privately and has recovered the actual facts will concealed and the patient will be said to have had a litt temporary delirium or something of that sort of no pa ticular consequence. The truth of what really has occurre will be concealed in future marriage or business relation and a deception set up the results of which are not unlike to be disastrous, whilst they certainly invalidate the accura of statistics.

Actual insanity is often veiled under the term "neura thenia," and it is, I know, far from infrequent for peop who are in depressed or excited states to be placed in wh are called "homes of rest" where they are isolated from t external world and are not allowed to communicate wi their families or to know what is going on outside the wal of the "home"—are, in fact, more restrained than th would be in any hospital or asylum, and that, too, wit out any system of inspection or authority to which appe can be made. This is a present-century evolution of the wa of treating insanity, especially in the best-to-do classes. do not know what can be said against it as long as t patients in these conditions are under careful medical supe vision, as long as it is proved that they have a better chan of recovery and actually do recover more quickly than if th were placed under certificates, but it cannot be denied th such practice is sailing dangerously near the wind and th when "accidents" such as suicide or some public scand occur the people concerned are more likely to get in trouble than if they had at the first faced the matter in strict medical and legal bearings.

Another mode of treatment that is now in vogue is hypnotism. Personally I have not much faith in hypnotism in actual insanity because of the difficulty there is in controlling the patient's attention, but I can quite understand that in proper hands it may be of the greatest use in early cases of obsession or insomnia where the symptoms if neglected would run into an actual insane state, or in cases where the presence of hysteria is doubtful. There seem to be people who are endowed with, or who have acquired, special powers of producing this condition, and though we do not yet know the exact nature of the hypnotic state there is little doubt that the production of it may induce rest and so prevent waste of tissue at a time when excessive katabolism is dangerous to mental equilibrium. Of course, we recognise that the person hypnotised really gives himself away and is not in any way affected by the will of the operator.

No department of medicine is in a greater transition state than is the whole question of insanity and what the developments will be during the next few years it is difficult to forecast. If we can hope for more direct accessibility to the brain we shall have made a great advance. That we shall ever know more perfectly than we do now the essential nature of mind and how it comes that a certain condition of action of brain tissue means (I do not say *causes*) the display of what we call consciousness is problematical, but we have still enough to occupy us in the investigation of the physiological, clinical, and anatomical truths which are at present merely theories as far as our explanations go.

I have already had to refer in not very satisfactory terms to the question of statistics in asylum reports. Some of the tables usually appended are good, others are of no value, and some even are misleading. With the great stress now laid on the importance of holding necropsies upon every patient who dies in an asylum it is possible to correct the diagnosis made during life by the facts ascertained post mortem, and if care is taken not to sign the medical certificate of death before the necropsy has been made we have a system for registration which may be pronounced as accurate as it is possible to make it, so that the death tables may be taken to be satisfactory and more useful probably than any other accounts of mortality, except perhaps those from the prisons. But as to the cures or recoveries the results given merely show that in the opinion of a certain medical man authorised by two of the committee such and such a person may be discharged. There is so great pressure on the accommodation and so much interference by the friends who exhibit great anxiety to take the patients away on the first remission of symptoms, and there is also so much legal difficulty in keeping a patient in during the convalescent stage, especially when the time for re-certification comes round, that it is to be feared that many are prematurely discharged. If we read the number of relapses that occur in those who are discharged and the short time that many remain out of the asylum before they have to be re-certified we can but conclude that the discharges were premature, and if so what becomes of the published statistics and how can we compare the results of to day with those of former times? The tables of "Recoveries" have to be received indeed with great suspicion and with them of course disappears, as regards reliability, the allied tables of "Length of residence of those discharged cured" because very often the people were not cured when they were discharged.

Another useless table is that giving the form of disease in those admitted and discharged, because this is merely a table of *symptoms* and if the same patients were under review the week after they would probably fall under an altogether different nomenclature. Again, the table giving the form of insanity among those remaining in the asylums as so many of "mania," so many of "melancholia," so many of "delusional insanity," &c., is really only correct for the particular day on which it is made, the next day the conditions may be quite different. If it were possible to have a sound pathological or etiological classification there would be a real gain in the statistics, but as at present reports are presented in which so many cases of mania or so many of melancholia are admitted, it may be truly said that they are not, as regards practical value, worth the paper they are written upon.

I know the difficulties that exist, how rarely the friends will give, or can give, a true history of the attack and of the cause of it. I have already spoken of the treatment in "homes" or at home of numbers of insane persons, and if, as is the case, these persons never come within the jurisdiction of registration, of what beyond a nominal value is the real value of statistics as to the percentage of insanity in the general population? The proportion of the *registered* cases of insanity to the general population is of course accurate, but the table of causes is a very misleading one and is most inaccurate.

The table of the proportion of suicidal and homicidal cases is merely a hypothetical and visionary one. It is taken chiefly from reports which are often unverified, often misinterpreted, and it has no practical value whatever. So little are asylum statistics valued by the men who have practically to deal with the subject that few trouble themselves to read those parts of the reports in which they are given. Their compilation is in many respects perfunctory; they should be revised and most of them should be abolished.

On the question of heredity I hold that there is much confusion. It by no means follows that because a person is insane enough to be placed in a lunatic asylum therefore his children are of necessity tainted with insanity: so much depends on the nature of the attack and on the age of the children at the time when the ancestral neurosis was established. That hereditary tendency to insanity does exist cannot be doubted, but that it does not do so to the extent generally believed is, I think, much nearer the truth.

Finally, I would insist upon the close connexion between the study of neurology and insanity. At the present moment these allied states are almost divorced. Most asylums are replete with good instances of "neurology," such as the various forms of sclerosis, of hysteria, of trophic muscular lesions, of forms of aphasia, &c., in addition to the mental impairment, but it is to be regretted that most of the former pass unnoticed. And conversely many neurologists find themselves in the presence of symptoms of insanity the practical knowledge of which they are little acquainted with. I hope that before long each hospital will have a good clinique of psychiatry and nervous diseases and that the combination will be more critically and scientifically studied than it is now. Much is to be hoped from the development of the hospital system of treating acute and early cases which will come into force when the contemplated system of reception-houses is accomplished, but all depends upon the liberal spirit with which the proposed changes are carried out, and much money has to be spent and much more energy to be developed before material progress in the treatment of lunacy in this country is assured.

An Address

ON

ACUTE PLEURISY WITH EFFUSION.

Delivered before the Middlesbrough and District Medical Society on Nov. 27th, 1901,

BY GEORGE R. MURRAY, M.A., M.D. CAMB., F.R.C.P. LOND.,
HEATH PROFESSOR OF COMPARATIVE PATHOLOGY IN DURHAM UNIVERSITY; PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

GENTLEMEN,—Formerly attacks of acute pleurisy with effusion were attributed to the action of cold, but the more our knowledge of the subject increases the more evident it becomes that cold in the great majority of cases can only be considered a predisposing factor, just as it is in the case of pneumonia, and evidence is steadily accumulating which shows that a large number of cases are the result of primary or secondary infection of the pleura by a microbe. We must not, however, rush to the other extreme and conclude that all cases are due to infection, for the following observations appear to indicate that cold may alone cause pleurisy in some cases. Dieulafoy[1] quotes an observation made by Lemarre at Saint-Germain. A high wall which was situated midway between the forage-store and the barracks was lowered to the height of one metre. The soldiers who had to carry bundles of hay or straw from the store to the barracks at once began to rest, while hot and perspiring, on this wall. While thus resting the right side of a soldier, though sheltered in other directions, was exposed to the north-east wind which was often very cold. An epidemic of right-sided pleurisy broke out among these men, all of whom recovered, some after aspiration and others without. They were forbidden to rest at this point and no more cases occurred. The regiment changed every six months and on the arrival of the next one the men again made use of the wall as a resting-place with the result that pleurisy again appeared, only to cease when they were forbidden to rest there. This experience was repeated several times with the same result. In all 50 cases of pleurisy occurred; fortunately, all recovered. It is difficult to avoid the conclusion that these cases were due to the cold wind blowing on the right side while the skin was perspiring.

---

[1] La Semaine Medicale, Nov. 20th, 1901.

The comparative pathology of pleurisy shows that in animals it may be due to cold. Outbreaks of pleurisy have been recorded in recently clipped horses which have been kept in the open all night. Duvieusart observed 100 cases of pleurisy, 60 of which were fatal, in a flock of 400 sheep which had just been shorn during a very cold February. None of these animals were tuberculous and the fluid effusion injected into guinea-pigs never produced tuberculosis.

I shall now consider the evidence which indicates the frequency of the infective origin of pleurisy with effusion in man. In any given acute case of pleurisy with effusion it is by no means easy to determine the exact nature of the infection. During the last few years, however, evidence has been steadily accumulating which shows that the great majority of cases are either tuberculous or rheumatic in origin or are due to the pneumococcus. The most important of these is certainly acute tuberculous pleurisy and by this term I do not mean a pleurisy occurring in a subject who is manifestly tuberculous already, but an acute primary attack in an apparently healthy subject. We have now abundant evidence that many of these cases are due to infection by the tubercle bacillus. The most conclusive evidence is afforded by the presence of the tubercle bacillus in the effusion. This is not easy to demonstrate, as the bacilli in the effusion are scanty and in some cases may be altogether absent from the specimen examined. Microscopical examination of the fluid is therefore of little use. Thus Ehrlich found the bacillus by microscopical examination in only two out of nine and Levy in not one out of 13 clearly tuberculous cases. Cultures may be prepared from the fluid but the results are often negative in undoubtedly tuberculous cases. Lemoine made cultures from 38 cases of pleurisy with effusion; in 28 of these the tubes remained sterile and yet 15 of these 28 cases ultimately turned out to be tuberculous. As other bacteria generally develop in cultures prepared from non-tuberculous cases the absence of growth in a tube inoculated from an acute effusion is regarded by many as strong presumptive evidence in favour of its tuberculous origin. Recently, Bezançon and Griffon have employed a new medium consisting of nutrient agar to which are added glycerine and rabbit's blood, spread on the bottom of an Erlenmeyer's flask. It is necessary to employ several flasks in each case and the colonies only appear after three or four weeks in the warm incubator at 37° C. Positive results are said to be obtained more frequently by this method.

The most trustworthy method of determining the presence of the tubercle bacillus is by inoculating a guinea-pig with the fluid obtained by aspiration. If the animal develops tuberculosis it is clear that the patient suffers from pleural tuberculosis. Netter[2] made inoculations with exudation from three different classes of cases. In 16 cases known to be tuberculous eight positive results were obtained. In 25 cases attributed to cold tuberculosis developed in the inoculated animals in 10 cases (40 per cent.). In 14 cases in which the pleurisy was evidently due to some other cause all the inoculations were negative. Le Damany[3] inoculated guinea-pigs with the exudation from 55 cases of pleurisy. In 47 cases (85 per cent.) the animals developed tuberculosis; in eight the results were negative, though four of these were inoculated from cases which gave clinical evidence of tuberculosis. It has been shown by Eichhorst[4] that it is necessary to take a large quantity of a serous effusion for inoculation experiments or else the results are not reliable. This is no doubt due to the fact already mentioned, that even in undoubtedly tuberculous pleurisy the tubercle bacilli may be sparsely scattered in the fluid. This observer found that when 15 cubic centimetres of fluid were used for inoculation more than 62 per cent. of the animals became tuberculous and only 10 per cent. if only one cubic centimetre was used. It was shown by Debove in 1891 that serous effusions often contain tuberculin which we know is a product of the growth of the tubercle bacillus. Still further evidence is afforded by the result of injections of tuberculin for diagnostic purposes. Thus, in the German Government report on the efficiency of tuberculin it is stated that 15 cases of pleurisy were tested with tuberculin and both a general and a local reaction followed in 13 (87 per cent.) of them.

There is further strong clinical evidence of the tuberculous origin of pleurisy with effusion The previous history of a case, as a rule, helps but little but the after-history is often most instructive. It is well known that a patient who has had pleurisy with effusion not infrequently develops tuberculosis, generally of the lung, later. Several series of cases have been published which show this relationship clearly. For example, Dr. A. G. Barrs[5] in 1890 ascertained that 21 out of 57 cases of pleurisy with effusion treated at the Leeds Infirmary during the years 1880–84 had died from tuberculosis. Hodges found that in 130 cases of primary pleurisy which were traced for seven years 40 per cent. became tuberculous. Fiedler found that of 92 cases of pleurisy with effusion 28 died in two years from phthisis, 43 had either definite tuberculous disease of the lungs or signs suggestive of it, and only 21 appeared to be healthy. Whitney[6] by adding together several published series of cases obtained a total of 310 cases of pleurisy, 178 (57 per cent.) of which subsequently developed tuberculosis.

Post-mortem evidence also points to the same conclusion, for Kelsh and Vailard[7] examined 16 fatal cases of pleurisy in the majority of which the effusion was serous. The subjects were in good health before the attack which had generally been attributed to cold and died during apparent convalescence. In every case miliary tubercles were found on the pleura. Dieulafoy[8] relates several similar cases of acute primary pleurisy with effusion in which the patients died suddenly during the attack and in which tuberculosis of the lung or pleura was found at the necropsy. If we take all these facts into consideration I think we may fairly conclude that fully one-half of all cases of pleurisy with effusion are due to infection of the pleura by the tubercle bacillus. This is an important conclusion and has a direct bearing on prognosis and treatment.

Another microbe which causes pleurisy with effusion is the pneumococcus. More commonly infection of the pleura with this microbe results in a purulent effusion, as when lobar pneumonia is followed by an empyema. Still, in some cases a serous effusion may occur with, or follow, a croupous pneumonia; thus, Prudden found the pneumococcus twice in six such cases which he examined. We may, however, have a pleurisy with effusion caused by the pneumococcus without any pneumonia at all. The following case is a good illustration of this.

The patient was a single woman, aged 33 years, who was being treated in the Newcastle Infirmary by Dr. G. T. Beatson's method for inoperable recurrent carcinoma of the right breast, when she had an acute attack of pleurisy with effusion. The breast had been removed by Mr. J. R. Morison on Nov. 6th, 1900. Recurrence took place 12 weeks after leaving the hospital, when she was readmitted. It was decided to adopt Dr. Beatson's treatment by removal of the ovaries and giving thyroid extract. Mr. Morison removed both ovaries on March 6th, 1901. On the 16th she was transferred to my care for the second part of the treatment. I may mention incidentally, though it does not concern us further here, that the treatment had a remarkable effect upon the recurrent nodules of growth, which rapidly diminished in size and almost disappeared. Some six weeks later, however, they returned and have since grown larger than ever. During the 14 days which followed the operation the temperature was only above 100° F. on two evenings—100·2° on the 8th and 101·4° on the 20th. On March 25th the temperature rose to 100° in the evening and the next evening to 103·4°. Two days later she complained of severe pain on the right side of the chest, which came on suddenly, and was increased by deep inspiration. Two days after this the apex beat was displaced outwards to the left, nipple line and there were absence of vocal fremitus, dulness on percussion, and absence of breath sounds over the lower part of the right side of the chest up to the fifth rib in the right nipple line in front and to the angle of the scapula behind. On April 1st the apex beat was in the fourth left intercostal space just outside the nipple line and the dulness extended up to the fourth rib in the right nipple line. No further increase in the physical signs took place. An exploratory puncture was made and a syringeful of clear serous fluid was withdrawn, from which cultures were made on agar-agar. After incubation a pure culture of numerous colonies was obtained of a diplococcus identical in appearance with the pneumococcus. The temperature was not normal until April 12th. The physical signs gradually diminished but on the last examination (on May 10th) the apex beat was internal to the left nipple line, the vocal fremitus was still slightly less at the right base than at the left, and there was dulness at the right base for three finger-breadths. The breath sounds were audible down to the right base but were less loud than on the left. Here we have a good example of an acute attack of pleurisy with effusion with 18 days' fever running a favourable course in which the effusion was absorbed without the aid of aspiration.

[6] Twentieth Century Practice of Medicine, vol. vii., p. 11.

[7] Quoted by Dr. J. K. Fowler in "Diseases of the Lung."

[8] Loc. cit.

It has been shown by Dr. J W Washbourn[9] that the constitutional symptoms of primary infection of the pleura by the pneumococcus may be just the same as those of lobar pneumonia, for which they are apt to be mistaken. Thus, in one of his cases there were herpes, high temperature, delirium, cough, and rapid breathing, yet at the post-mortem examination the lung was found to be unaffected while the right pleural cavity contained 54 ounces of pus in which the pneumococcus was found. The occurrence of acute primary empyema with such symptoms indicates the importance of exploratory punctures of the chest in cases in which the physical signs are not conclusive.

Other bacteria which have been found in serous pleural effusions are the typhoid bacillus, the streptococcus pyogenes, and the staphylococcus pyogenes, though when the two latter organisms are present the effusion is usually, but not always, purulent.

In empyemata bacteria are commonly present. In old empyemata, however, bacteria may die and the pus become sterile. I remember a child (who was admitted to University College Hospital under the care of Dr. S. Ringer when I was house physician there) with a very large empyema of long duration in which tubes inoculated from the pus at the time of the operation and incubated remained quite sterile. I have once found tubercle bacilli in pus discharged from an empyema which had been opened and drained some time previously. This was in a patient (whom I saw with Dr. H. S. Baumgartner) who was suffering from tuberculous disease of the lung on the same side and whose sputum also contained tubercle bacilli. In another case of empyema I found the staphylococcus pyogenes albus and in others the diplococcus. In addition to these three micro-organisms the streptococcus pyogenes has frequently been found and the typhoid bacillus and bacillus coli communis have been found occasionally.

Mr. Bilton Pollard[10] has recently pointed out that the course of an empyema varies according to the micro-organism present and that a bacteriological examination of the pus is a useful aid to prognosis. He found that pneumococcal empyema runs the most favourable course. This variety occurs most frequently in children in whom empyemata are generally benign. Staphylococcal empyemata begin more insidiously and run a less acute course, while streptococcal empyemata develop rapidly, run an acute course, and are accompanied by severe toxic symptoms. Mr. Pollard considers that any pleural effusion, even if only slightly turbid, which contains streptococci, should be regarded as an empyema and treated as such.

In the case of serous effusions it is also important to ascertain the exact cause. We will now consider how this is to be done. The actual symptoms and physical signs will not give the required information. In some cases a careful inquiry into the past history may show that there has been, perhaps, an obstinate bronchitis, a slight hæmoptysis, a fistula in ano which was cured by an operation, enlargement of the cervical glands in childhood, or possibly disease of the hip-joint. The actual attack may have been preceded by vague ill-health, some loss of strength, and decrease in weight. Any of these would indicate that the pleurisy was in all probability tuberculous. Cultures prepared from the fluid drawn off in a sterilised syringe will show if the effusion is caused by the pneumococcus, the streptococcus pyogenes, or the staphylococcus aureus. The tubercle bacillus takes long to grow, so that absence of growth at the end of 48 hours is in favour of tuberculosis. Culture tests are, however, difficult to carry out in private practice. Inoculation tests require a special licence. The fluid removed from the chest has been found to cause agglutination of a culture of tubercle bacilli, but the test is much more difficult to carry out than Widal's test for enteric fever and as yet has not been sufficiently simplified for regular use. Courmont obtained a positive reaction in 23 out of 31 cases in which he used the fluid from the pleura and in 18 out of 22 in which he employed the blood for the test. The tuberculin test might also be employed, but it has not as yet come into general use and might give unreliable results as long as the temperature was high in acute cases.

A still more recent method which was introduced by Widal and Ravaut and described lately by Dieulafoy,[11] which deserves extended trial, is by the microscopical examination of the deposit obtained by centrifugalising some of the fluid withdrawn by an exploring syringe. A drop of the sediment is spread on a cover-slip and stained with thionin or other suitable stain and examined under the microscope. It has been found that pleural effusion may contain red blood corpuscles, leucocytes with multipartite nucleus, large mononuclear cells, lymphocytes and endothelial cells, and it has been found that different cells preponderate in different types of effusions. Thus in passive effusions large endothelial cells are found almost exclusively or greatly in excess of any red blood corpuscles or leucocytes which may be present. In pleurisy caused by the pneumococcus or streptococcus large polynuclear and mononuclear cells preponderate. In the acute pleurisies which we have seen every reason to regard as tuberculous the cells are almost entirely lymphocytes with some red blood corpuscles. I have had as yet no personal experience of this method but mention it as a simple one which, if reliable, may be of great service. If by one or other of these methods we arrive at an exact diagnosis we shall in the case of a tuberculous pleurisy expect the effusion to be absorbed, though probably paracentesis may be required once or oftener, and we shall frame a prognosis and after-treatment, bearing in mind the danger of tuberculosis of the lung at a later stage. If the effusion is due to the pneumococcus the prognosis is favourable and the duration of the attack will probably be from one to three weeks. The fluid may be entirely absorbed or if paracentesis is required it will be only once. If the streptococcus is found the attack will probably be acute and severe. The fluid, serous at first, soon becomes turbid and often purulent later. The duration of the attack may be long, extending to several months. The fluid soon accumulates again after aspiration, so that incision and drainage are usually required as for empyema.

Of the symptoms of an attack of pleurisy with effusion little need be said, as we have already described some of them in detailing the case of diplococcus pleurisy. The acute onset, with repeated chills, rather than a rigor, and the sharp stabbing pain in the side are characteristic. I think it is probable, however, that a rise of temperature may occur even before these symptoms. The relief of the pain when the serous exudation takes place and separates the two layers of the pleura is also a common feature. The physical signs have been so often described that they do not require further consideration here. I would emphasise one point, however, and that is the presence of typical bronchial breathing instead of the usual absence of breath sounds over a pleural effusion in some cases. This was well illustrated by a case of Hodgkin's disease in a woman (whom I saw with Dr. W Murray and Mr F Page) who had enlarged lymphatic glands in the posterior mediastinum which caused a left hydrothorax. In this case, which I aspirated on several occasions, there was always typical bronchial breathing when the effusion was large. It disappeared each time after tapping, only to return as the pleural cavity refilled. This is more frequent in children than adults but is a common cause of error

It not infrequently is necessary to make an exploratory puncture, either to ascertain if fluid is present in the pleura in cases in which the signs are doubtful or to determine the nature of the fluid itself. I do not by any means advocate the indiscriminate use of an exploring syringe in all cases, but there is no doubt that in a large number of cases valuable information is obtained by its use and on the whole it is used less frequently than it should be. The ordinary hypodermic syringe which is sometimes employed for making an exploratory puncture is unsuitable owing to its small capacity, as it holds only about 20 minims, and the very small bore of the hollow needle attached to it. The ordinary exploring syringe which holds one drachm is quite small enough for the purpose. On the whole, the simple pattern made just like a hypodermic syringe, but at least three times as large, is the most convenient. The hollow needle should be not less than three inches long and should have an internal diameter of not less than one-sixteenth of an inch. It is necessary to see that the needle is strong and has no flaw in it. Such a needle as this, when fixed on to the syringe held in the hand, ought to be able to bear a lateral strain of one pound in any direction near the point. This is easily tested, either by a one-pound weight or by a spring balance. The syringes which are supplied for the injection of antitoxic serum should never be used to explore the chest, as I have known the needle to snap off short. The needle must always be sterilised just before use. This may be done in several ways. It has been shown by Professor A. E. Wright of Netley that hot oil may be used in the following manner. Some olive oil is heated over a flame until a temperature is reached at which a crumb of dry white bread turns brown when dropped into it. If the syringe and needle are then washed out three times with the oil they will be thoroughly sterilised, however septic they may have been before.

[10] Clinical Journal, Feb 27th, 1901, p. 203.

[11] Loc. cit.

Practically, I find the following method is reliable. The needle is put into a test-tube and enough cold water is added to cover it. This is then heated over a spirit lamp till it boils and is kept boiling gently for one minute. The tube is then inverted over a dish containing 1 in 40 carbolic lotion, so that the needle falls directly into this and is kept sterile till it is wanted. The syringe should be washed out two or three times with the carbolic lotion. If cultures are to be made from the fluid both syringe and needle should be boiled in a pan. I have tested the results of boiling in this way with a laboratory culture of the staphylococcus pyogenes aureus as follows. A broth culture of this micrococcus two days old was taken, which was turbid with the growth, and on microscopical examination was found to contain plenty of cocci. Some of the broth was drawn through a cannula which was also immersed in the culture, so that the micrococci were brought in contact with all parts of it. The cannula was then put into a tube of cold water and boiled one minute. It was then transferred to a tube of sterile broth for a short time, after which the tube was placed in the hot incubator. This tube of broth remained sterile. Three loopfuls of the water in which the cannula had been boiled were rubbed on the surface of an agar tube which was incubated but no growth took place. As a control the same experiment was repeated *without* boiling the water in the tube, the result being that an abundant growth appeared in the broth tube in which the cannula had been dipped and many colonies of the staphylococcus pyogenes aureus appeared on the surface of the agar tube inoculated from the tube of water.

The disinfection of the skin is also important. It should be well washed with soap and water and then scrubbed with cotton-wool soaked in 1 in 20 carbolic lotion. This I find to be sufficient and this conclusion is supported by the following tests. In the case of diplococcus pleurisy already described, before the skin was cleaned for the puncture a sterilised platinum loop was rubbed over it at the site selected and then over the surface of an agar tube. The skin was then washed and scrubbed with the carbolic lotion and the platinum rubbed over it as before, and a second agar tube was inoculated in the same manner. Both tubes were incubated and by the following day 213 colonies of staphylococcus pyogenes aureus and albus had developed in the tube inoculated from the skin before cleaning and none at all in the other one. It may be said that the absence of growth was due to some of the carbolic lotion being transferred to the tube by the platinum wire and inhibiting the growth of any organism. That this was not the case, however, was proved by inoculating the tube with the micrococcus growing in the first tube, after which it grew abundantly in the second tube also. If a puncture had been made in this case without antiseptic precautions there would have been a considerable risk of carrying some of the pyogenic cocci from the surface of the skin with the needle into the pleural effusion and thus of converting a serous effusion into an empyema. In another case of a man who had aortic disease and left hydrothorax I took cultures in the same manner, with the exception that the carbolic lotion was washed off with cotton-wool and hot water, both of which had previously been boiled. In this case 13 colonies developed in the tube inoculated from the skin before disinfection and none in that done afterwards.

In selecting the point at which to make a puncture we must be guided by the physical signs, but in the majority of cases with signs of fluid at the lower part of the pleura the eighth or ninth intercostal space in the line of the angle of the scapula is the most convenient position, with the patient sitting up in bed. If it is necessary to explore with the patient lying down the mid-axillary line in the sixth or seventh intercostal space will be more convenient. The skin should always be frozen with the ethyl-chloride spray, as patients have often assured me that without it a puncture may be very painful and with it they scarcely feel it at all.

In making an exploratory puncture the needle should be just pushed through the parietal pleura at first and the handle of the syringe withdrawn about one-third of its length. If no fluid appears in the syringe push the needle in another third, withdraw the handle another third, and if still there is no fluid push it in as far as it will go and draw out the plunger to the full limit. If, instead of doing this, the needle is pushed right in at first it may pass through and beyond a layer of fluid and miss it altogether. The following case is a good illustration of this.

A man, aged 29 years, was admitted under my care at the Newcastle Royal Infirmary on Feb. 1st, 1897. Six weeks previously he received a sharp blow on the left side of the chest and had pain for several days, which then subsided. Three days before admission he was seized with severe pain in the left side of the chest and difficulty in breathing. On admission no definite physical signs were present. On the 10th there were loss of vocal fremitus, dulness on percussion, and loss of breath sounds below the level of the angle of the left scapula behind. The heart's apex beat was midway between the nipple line and the sternum. The following day the dull area was explored with a needle but no fluid was obtained. The dulness increased upwards to the middle of the scapula and the patient became cyanosed. The chest was again explored on the 12th and some clear serous fluid was obtained and the natural conclusion drawn was that there was a serous pleural effusion and not an empyema, as had been suspected. Three days later, however, he expectorated 14 ounces of foul pus which was found to contain an enormous number of micro-organisms, streptococci and pneumococci among them. Two days later the chest was again explored just below the angle of the left scapula and pus was withdrawn. The pleura was opened and drained but the patient died the following day. At the necropsy, in addition to the empyema which had partly discharged through the lung, the posterior part of the pericardium was found distended with five or six ounces of clear serous fluid, so that there was only about one inch of compressed lung between it and the chest-wall, the two layers of pleura at that point being separated by only a thin layer of pus. Thus in exploring the chest the needle had evidently passed right through the empyema into the distended pericardium, from which the serous fluid had been withdrawn through the empyema. If in this case the needle had been thrust just through the chest-wall at first the pus would have been tapped and the mistake avoided.

If no fluid appears in the barrel of the syringe the needle should be withdrawn and the contents of the needle itself driven out on to a glass slide. It should be noted if any smell can be detected and the fluid thus obtained should be examined under the microscope. In some cases of empyema the pus may be viscid and will not flow through the needle. In such cases the microscopical examination of the contents of the needle will often reveal its presence. In making the puncture it is important to note the resistance offered to the entrance of the needle and also to move it about somewhat so as to ascertain if the end is free in a cavity filled with fluid or has penetrated a solid. In this way the presence of a thickened pleura or a fibroid lung may sometimes be ascertained.

In all cases of acute pleurisy rest in bed is necessary. At the onset treatment is directed to the relief of the acute pain. For this purpose hot applications, linseed or linseed and mustard poultices, and belladonna fomentations are useful. Dr. F. T. Roberts's plan of strapping the affected side so as to limit the respiratory movements gives great relief in many cases. The application of a few leeches to the side, though now seldom employed, is certainly useful. If the pain is very severe a hypodermic injection of morphia gives prompt relief. As soon as exudation takes place the inflamed pleural surfaces are separated and the pain disappears. As soon as this occurs it is important to give a saline aperient, sulphate of magnesium or sodium in two or three drachm doses each morning, so as to ensure the passage of two or three liquid motions. 20 grains of sodium salicylate three times a day are often useful in early effusions; and it has been shown by Rosenbach and Pohl that in cases treated with this drug it is found to be present in the pleural effusion, whether it be active or passive in origin. At the end of a week or ten days, when the more acute part of the attack is over, iodine is of service in aiding the absorption of the effusion by the lymphatics. We can give tincture of iodine in five-minim doses, iodide of potassium in from five- to ten-grain doses, or iodoform in half- or one-grain doses. At the same time it is advisable to rub a drachm of 10 per cent. oleate of mercury into the affected side each day. Hay's method of treatment, in which the patient is restricted to half a pint of liquid in the 24 hours, while from half an ounce to one and a half ounces of Epsom salts in a concentrated form are given each morning an hour before breakfast, is highly recommended by Osler.

In many cases of pleurisy with effusion the question arises as to whether the fluid should be removed or not. Under certain conditions this has to be done without delay. In all cases of large pleural effusion at any stage in which there is dulness all over one side of the back of the chest, and dulness up to the clavicle in front, aspiration should be carried out at once; it should never really be deferred so long, as it is better to remove some of the fluid as soon as dulness extends above the level of the fourth rib in the nipple line in front. In these large effusions delay is dangerous, as sudden death sometimes occurs. The physical signs, however, do not always indicate the amount of fluid which is present, so that in cases in which the area of dulness is less than that just indicated immediate aspiration is required if there are marked dyspnœa on slight exertion, cyanosis, palpitation, irregularity of the pulse, or signs of œdema of the opposite lung. In cases in which the effusion is moderate in amount and produces no urgent symptoms there is no necessity to remove it during the first week or 10 days. A moderate effusion is probably useful in the early stages of an acute attack of pleurisy, as it separates the two layers of the pleura, allows the lung to retract, and lessens the respiratory movements. As a result of this the inflamed serous membrane is kept at rest as much as possible. The two surfaces are prevented from rubbing against each other and the pleura is placed under conditions which are favourable to recovery.

If aspiration is carried out at this early stage we are simply removing these favourable conditions, nor do we attain our end as the fluid is apt to reaccumulate. If at the end of a week or 10 days there is no diminution in the effusion recovery will be hastened by aspiration; if, on the other hand, absorption has already commenced it is not required. For removal of fluid from the pleural cavity Potain's aspirator is by far the most useful instrument. In urgent cases, where the aspirator is not at hand, it may sometimes be necessary to use a simple trocar and cannula with an indiarubber tube, but this is unsatisfactory.

All I have already said with regard to the exploring needle applies equally to the cannula. This should have a diameter of from one-sixteenth to one-tenth of an inch and should be sterilised along with the trocar and stopcock, boiling in a pan of water for at least a minute, and then transferring to 1 in 40 carbolic lotion until required. If a test tube is used for boiling the trocar should be passed through the stopcock before boiling and the cannula affixed afterwards. The hands should be washed in soap and water and then in 1 in 20 carbolic lotion. If the patient is able to sit up the puncture should be made in the eighth or ninth intercostal space below the angle of the scapula. If the patient is feeble or is liable to faint he should lie with his shoulders raised by a pillow and the puncture should be made in the sixth or seventh intercostal space in the mid-axillary line. The skin should be cleaned and frozen just as for an exploratory puncture. Just before the puncture is made the bottle attached to the aspirator should be partly exhausted by about half-a-dozen draws with the air-pump. As soon as the trocar has penetrated the pleura it should be withdrawn and the fluid flows through the cannula into the bottle. Aspiration is best carried out slowly, so as soon as the flow into the bottle ceases it is best to keep on drawing just sufficient air out of the bottle and to keep up a steady flow so that 10 minutes are allowed for the removal of each pint, a rate of flow which has been found by Fraentzel to obviate the disagreeable symptoms which sometimes occur when the flow is more rapid. The amount of fluid which should be removed varies, of course, in different cases. It is not advisable to attempt to remove all the fluid at a first aspiration and as a rule not more than two pints should be drawn off at one sitting. If during aspiration the patient begins to cough violently or complains of pain in the chest or faintness it is advisable to stop and to withdraw the cannula. The opening should be closed with a small piece of antiseptic wool and collodion.

A marked fall in the temperature follows aspiration in some cases, in addition to other signs of improvement. Thus, a man, aged 22 years, was admitted under my care at the Newcastle Infirmary on the seventh day of an attack of pleurisy. There were absence of vocal fremitus, dulness on percussion, and absence of breath sounds over the lower part of the right side of the chest as high as the upper border of the fifth rib in the nipple line in front and as high as the middle of the scapula behind. The apex beat was displaced to one inch outside the left nipple line. The temperature was 103° F. in the evening of the eighth day. On the ninth day 26 ounces of clear serous fluid were removed. After the tenth day the temperature did not rise above 101° but still rose to 100·8° in the evening up to the eighteenth day. On the nineteenth day 48 ounces of fluid were removed, after which the temperature did not again rise above 99·2° in the evening.

Aspiration is of little use, as a rule, in empyema except to give temporary relief. It is true that occasionally an empyema does not fill up again after aspiration, but this is rather the exception, and in all cases incision and drainage of the pleura should be carried out as soon as possible. In one case of double empyema which I aspirated to relieve urgent dyspnœa aspiration of one side emptied both sides, showing that there must have been a communication between the two pleural cavities. The child died but no post-mortem examination was made.

After aspiration the patient should remain in bed for at least two or three days. After that he may be allowed to get up as soon as his general and local condition allow it. The after-treatment of a case of pleurisy with effusion is of great importance and is practically the same whether the fluid has been absorbed or removed by aspiration. The great object in view is complete re-expansion of the lung. This is often difficult to attain, especially in the case of poor patients who are unable to carry out the most suitable treatment and in whom we often find signs of deficient expansion at the base of the lung long after the acute attack. As soon as the physical signs indicate that the fluid is being absorbed, or three or four days after paracentesis, it is advisable to start respiratory exercises which increase the intra-pulmonary pressure and so assist the expansion of the lung. For this purpose the simplest plan is to instruct the patient to inflate an ordinary indiarubber football bladder by blowing into it, as has been recommended by Mr. Bilton Pollard[13] in the treatment of collapsed lung after operation for empyema. The patient should be instructed to inflate the bladder as much as possible some six times in succession three or four times a day. The influence of thus making a respiratory effort against resistance in expanding the lung is easily illustrated by making the patient inflate the bladder while the chest is being aspirated just when the flow into the bottle ceases; a steady stream will at once begin to flow again as a result of the increased intra-pleural pressure. Dr. Osler recommends the use of Wolff bottles, an arrangement of bottles fitted with tubes through which water can be driven by blowing alternately from one into the other. The indiarubber bag is, however, much more simple and can easily be carried in the pocket.

A prolonged convalescence is advisable after a pleurisy with effusion. The importance of this is easily realised when we consider the great frequency of tuberculosis in these cases. As much time should be spent in the open air as possible and a gradually increasing amount of walking exercise should be taken in addition to the continued use of the pulmonary exercises. Exercises with dumb-bells and Indian clubs are also useful. The patient should be sent to as high an altitude as possible. Where the circumstances of the patient permit of it there can be no doubt that residence for a couple of months in the Alps, at a height of from 4000 to 6000 feet, gives the best results. The deeper and more rapid respiration which is necessary at this height gives better results in restoring the full expansion of the lung, in my experience, than any other method of treatment. I am inclined to think that those who are able to carry out this climatic treatment are less liable to develop pulmonary tuberculosis at a later date than those who do not.

---

[13] Loc. cit.

The following two cases illustrate the advantage of a visit to high altitudes. The first was that of a young man, aged 25 years, whom I saw with Mr. A. H. Thompson of Darlington on May 9th, 1900. The patient had an acute attack of pleurisy with effusion on the right side. As the temperature was high and the effusion was not sufficiently large to necessitate immediate removal we decided that it was not advisable to aspirate then. When I saw him again 10 days later the effusion had not diminished and he was nervous, as he had fainted when an exploratory puncture was made. We decided that the fluid should be removed and aspirated about a pint while he was lying back on the pillows. After this he steadily improved and later spent some time in the hills at the head of Weardale. On July 13th he was much better but still was easily tired and had some dyspnœa on exertion. On examination there was still some impairment of resonance at the base of the right lung behind. We advised him to go to Arosa, in the Alps, where he spent two months at an altitude of 6000 feet. As a result of this the lung expanded fully and when I examined him on his return movement, percussion note, and breath sounds were quite normal again. He spent last winter in Egypt and when I examined him recently the condition of the lung and pleura was quite normal. He had occasionally slight pain with very deep respirations owing to adhesions which are sure to be left after such an attack.

The second case was very similar; it was in a man about 10 years older than the other case, whom I saw several times with Mr. T. A. McCullagh of Bishop Auckland. The patient had an acute attack of pleurisy with effusion on the right side which we found necessary to aspirate. After this he steadily improved and as soon as he was strong enough he spent some weeks at high altitudes, chiefly over 4000 feet, in the Alps. The result was most satisfactory, as complete expansion of the lung took place, so that no difference could be detected between the two sides of the chest.

A CONTRIBUTION TO THE STUDY OF TROPICAL ABSCESS OF THE LIVER.[1]

By RICKMAN J. GODLEE, M.S. Lond., F.R.C.S. Eng.,
HOLME PROFESSOR OF CLINICAL SURGERY, UNIVERSITY COLLEGE, LONDON.

In the course of an experience of tropical abscess of the liver somewhat large for an English surgeon, though ridiculously small as compared with that of those practising in the tropics, I have been led to think about the disease and its complications, and I trust that the following contribution to its study may be, if disjointed, not therefore without interest. Possibly it may elicit some useful comment and criticism and it is on this account that the statements contained in it are somewhat dogmatic. I will deal first with some of the complications.

Perihepatitis, usually perihepatic peritonitis, is an almost invariable accompaniment of tropical abscess and must always exist to a greater or less extent when the abscess reaches the surface of the liver, but it is astonishing how little there is in some cases even when the matter has approached within perhaps half an inch of the surface. If there be no adhesions the introduction of an exploring trocar or an aspirator needle into the liver will be probably immediately followed by the escape of pus into the peritoneal cavity. Supposing the needle has been introduced for the sake of discovering the existence of an abscess and the operation for its evacuation be immediately proceeded with there may yet have been time for a quite considerable quantity of pus to have escaped in the few minutes which have elapsed before the peritoneum is reached. It is even possible to mistake this free pus for the abscess itself. The further exploration of the liver under these circumstances is essential. But first the peritoneal cavity in the neighbourhood of the puncture should be carefully sponged, for although the pus may contain no other organism than the amœba coli and need not necessarily give rise to septic peritonitis there is no security that streptococci or staphylococci or bacterium coli commune may not be present. It is scarcely possible under these circumstances to sew the liver up to the abdominal wall, as each stitch will most likely enter the abscess cavity and the stitch holes will leak. It is safer, therefore, to pack round the part where the incision is to be made before the abscess is actually opened and after the opening has been made to manipulate the parts as gently as possible. Perihepatic peritonitis is the cause of the acute pain that is often met with as distinguished from the typical liver pains. This pain is, of course, superficial, and is accompanied by acute tenderness easily elicited by even light percussion. Peritonitis occurs often in definite attacks, accompanied by fever and vomiting, and often yields a useful physical sign—i.e., *friction,* which may be felt with the hand and heard with the stethoscope over the liver. It exercises a protective effect by shutting off the part into which an abscess is pointing, so that when rupture occurs a sub-diaphragmatic abscess results, and not a general peritonitis.

As might be expected, peritonitis most commonly affects the convex surface of the liver which thus often leads to the adhesion in whole or in part of this surface of the liver to the diaphragm. When this has occurred an enormous amount of pus may accumulate in the liver without giving rise to any enlargement downwards and the enlargement upwards may only be indicated by partial dulness in the lower part of the chest; the dulness is least marked when the lung is adherent to the pleura because the lung cannot be then displaced upwards by the approximation of the diaphragm to the chest wall. Perihepatic peritonitis may also occur on the under surface of the liver and may then give rise to very serious results. The stomach, duodenum, and colon may become firmly adherent to the liver and after the abscess has been evacuated the consequent contraction may lead to considerable displacement of these viscera, giving rise to such troubles as dilated stomach from kinking of the duodenum. But it is a much more serious thing if the transverse fissure and the small omentum have been the seat of the peritonitis, for any one or all of the hepatic ducts may be partially or completely obstructed. I have recently seen with Dr. P. Manson a case which bears out this statement.

A man, aged 35 years, who had been in India almost continuously since 1887 and had had some pretty severe attacks of fever, began to have hepatic troubles following dysentery in May, 1900. The special points in his illness were that he had had several attacks of acute pain and indigestion, accompanied with high fever; and that an unsuccessful attempt to open the abscess through the chest wall in the lower axilla had been made in Madras in May, 1901. It will be observed that the history suggests a good deal of peritonitis. I opened the abscess without difficulty through the old scar in July, 1901, and during convalescence, which was rather tedious, there was from the first a rather large quantity of bile in the discharge. This escape of bile is not uncommon; it indicates that a bile-duct of some size communicates with the abscess, and though it delays healing it seldom gives rise to trouble. In this case, however, after the abscess had contracted and pus had ceased to flow bile still came from a small opening in the scar. After a while it nearly stopped. But at the end of September, after some abdominal pain, all the bile came through the wound and the stools became white. On Nov. 7th the flow of bile ceased and the patient became intensely jaundiced. Knowing the danger from hæmorrhage of operating on a jaundiced patient I passed probes into the wound and fortunately re-established the flow of bile by this channel, and when the jaundice had diminished, and after the administration of large doses of chloride of calcium, I opened the abdomen on Nov. 28th and found the matting together of the viscera which I have described above. It was quite hopeless to free the common bile-duct from the dense surrounding adhesions, as I had hoped to do, and so, as the gall-bladder, though not distended (because the bile was escaping through the wound), contained bile, I anastomosed it with the first part of the duodenum, using a Robson's bobbin. It was a difficult task. I ought to have waited still longer—i.e., until the jaundice had completely disappeared—for after a few days hæmorrhage occurred in the wound, and to the consequent stretching of the parts I attribute the partial giving way of the junction and the escape of bile and duodenal contents through the abdominal wound for a while. At last, however, the leak stopped and the wounds healed, the stools becoming of normal colour and the patient's health soon re establishing itself. I must add, however, that he had an attack apparently of indigestion in January, 1902, followed by the escape of bile for a few days from the abdominal wound. But this has again closed and at present he is quite well. His condition for the next six months will be watched with interest.

---

[1] A paper read before the Royal Medical and Chirurgical Society on May 13th, 1902.

The escape of the whole of the bile through the wound is fortunately not of common occurrence. I have never before met with it in cases of tropical abscess though I have seen it in hydatid of the liver. It does not necessarily lead to loss of appetite or difficulties in digestion, but it sooner or later causes emaciation which may become extreme. I have seen bedsores form over the projecting angles of the ribs and angles of the scapulæ. I am permitted by the kindness of my friends Dr. Manson and Sir W. H. Bennett to mention the only other two instances which I have heard of in connexion with tropical abscess, and I would suggest that in fatal cases the same condition as that which occurred in the one that I have just described will be met with. In Dr. Manson's case (Case 1) the patient died after four months in a state of extreme emaciation though the fistula was apparently beginning to close, and in Sir William Bennett's case (Case 2) the sinus gradually closed after seven months and the patient made a complete recovery. In connexion with this subject reference may be made to cases, with which all will be familiar, where there is complete obstruction to the common bile-duct either from calculus, tumour, or inflammatory adhesions. These patients do not, as far as I have seen, emaciate; on the contrary, their nutrition may remain fair for years and it is quite remarkable how long the fatal event may be delayed.

It has been shown by the beautiful observations of Klein that the direction of the flow in the lymphatics of the diaphragm is upwards. As might, therefore, have been expected, pleurisy is a very common accompaniment of tropical abscess. It is a useful diagnostic sign. It is also a note of warning. Rupture into the pleura is in my experience one of the most dangerous outcomes of this disease. I could, if it were advisable, give more than one example of this catastrophe being followed by the most extraordinarily rapid pleural effusion. In one, indeed (Case 3), though I saw the patient within 24 hours of the rupture of an abscess which had for so many months remained dormant that its very existence had been doubted, the patient appeared to be moribund, and the pleura contained an enormous amount of fluid. But even when the pleura is opened at once, if the lung have not previously contracted adhesion to the chest wall, it is not unlikely that it may collapse against the spine and never expand again, and the most extensive Estlander's operations may fail to effect a cure. The patient, therefore, who has extensive pleural adhesions is saved from very grave dangers.

It would often save trouble and anxiety if the presence or absence of such adhesions could be determined. This is, however, notoriously difficult and often impossible, which is my excuse for mentioning two aids to diagnosis which have not, I think, received sufficient attention. 1. The upper level of the dulness caused by a liver which is enlarged upwards is, speaking generally considerably lowered when the patient is placed on his left side. If, however, the lower part of the pleural sac is obliterated by adhesions this does not occur, because the lung cannot be sucked down into the pleural sinus by the falling away of the liver—that falling away which so frequently causes pain when the patient attempts to lie on the left side. 2. In very thin people, even when the parts are normal I have pointed out[3] that it is often possible on careful inspection to see the lower margin of the lung on the right side move upward and downward during respiration. It may sometimes be observed on the left side, especially if the spleen be enlarged or if there be a great enlargement of the left lobe of the liver, or, indeed, any tumour in this situation, and on the right side it is more obvious when the liver is enlarged than when it is of normal size. This sign requires somewhat careful inspection for its discovery and it is only of use in emaciated or very thin subjects. If it be present it is a certain proof that there are no adhesions in this situation and that there is little or no pleural effusion.

Whilst writing this paper I had under my care a young woman in the last stage of emaciation from advanced actinomycosis, in whom I was able to demonstrate this phenomenon to spectators standing at some little distance from the bed. It was in her visible on both sides. It has been doubted by physiologists whether on deep inspiration the lung ever reaches the bottom of the pleural sinus. Careful observation of this patient showed that on very deep inspiration the lower border moved quite as far as the anatomical limit of the pleural cavity.

Though not quite germane to the subject it may not be out of place to throw out the suggestion that when the liver is much displaced downwards by a pleural effusion and there is no corresponding displacement of the heart outwards it is almost certain that the base of the lung is not adherent to the diaphragm and that under these circumstances it may be almost impossible to say whether the fluid is above or below the diaphragm.

In connexion with the question of adhesions I desire to make a practical suggestion. If the incision for opening the abscess has necessarily to pass through the pleura below the lower border of the lung it is often difficult or impossible to tell whether the cavity is obliterated by lymph or not. I have more than once cut down through both layers of the pleura and as no air has entered I have gone on to incise the diaphragm and liver. On withdrawing the finger, however, the ominous sound made by air rushing into the chest has shown that the two layers of the pleura were at first only held together by the attraction of cohesion or by very feeble adhesions, and a laborious process of stitching up the hole had to be undertaken. The right way to proceed, if there be any doubt, is to cut through the diaphragm across its fibres at the part nearest its costal attachment and to sew up a flap of the muscle to the intercostal muscles at the opposite end of the wound. The incision into the abscess can then be undertaken without fear of producing pneumothorax. By adopting this precaution I do not expect to meet with the above-mentioned accident again.

Pleurisy may lead to serous effusion, or to empyema, without any rupture of the liver abscess through the diaphragm, and such an effusion may keep up the temperature after the successful evacuation of the hepatic abscess. I once opened a large tropical abscess on an Indian army surgeon who was in an extremely exhausted condition. There remained some dulness in the back and the temperature did not fall to normal. The removal by aspiration, several days later, of a few ounces of clear fluid was immediately followed by disappearance of the pyrexia and from this time the patient made an uninterrupted recovery. On another occasion, when the physical signs and symptoms were almost the same, the fluid was pus and an equally good result followed the insertion of a drainage-tube into the pleura. A less successful result followed in the case of a young officer whom I saw with Dr. Ringer and whose abscess I had opened in the lower axilla. Repeated attempts at aspiration of the chest were unsuccessful because there was much recent lymph as well as fluid in the pleura. In the hope of securing better drainage I made a second incision into the abscess behind, and in doing so found that I had opened the pleura and a considerable quantity of clear fluid and large masses of lymph escaped. Thinking that some of the pus from the abscess had probably entered the pleura I therefore placed through this second opening one tube into the abscess and one into the pleura, but I am sure it would have been better to have sewn up the opening in the pleura and to have left this cavity for treatment later, for the recent pleural adhesions gave way owing to the violent coughing of the patient, the lung collapsed and a general pneumothorax was produced. The case was a very septic one and a fatal result was probably inevitable but I think that it was hastened by the pleural complication. I said that the existence of friction was an *ominous* sign, for although rupture into the lung as everyone knows often leads to a rapid cure of the disease no one who has seen the disastrous results that may ensue would dream of waiting for it to occur. *When there is marked pleural friction, therefore, exploration of the liver should be made without delay.*

I am thus led to the next part of my subject.

[3] Brit. Med. Jour., Oct. 6th, 1900, p. 997.

Changes that take place in the lungs.—It is obvious that in every case in which an abscess bursts into the lung a certain amount of lung tissue must be destroyed and an abscess of greater or smaller extent must be formed. In those which recover in a short time this is a negligible quantity. But it is often far otherwise. The next most favourable cases are those in which a small abscess forms in the lower part of the lung either in front or behind. Most commonly the signs of cavity will be met with below and to the inner side of the right nipple; but the cavity not infrequently occurs behind, and in rarer cases a liver abscess bursts into the left lung and forms a cavity there. At the end of this paper will be found an account of cases illustrating each of these conditions (Cases 4, 5, and 6). If such abscesses are opened as soon as they are discovered it is probable that they will heal readily. But if operation is delayed a series of phenomena may occur that are not unlikely to give rise to a very chronic condition which may end fatally. These abscesses do not behave like those resulting from pneumonia, injury, or tubercle, but have a peculiar tendency to burrow by means of long and intricate tubular processes which are very difficult to follow up and drain and may lead to the gradual destruction of large areas of lung tissue. I have seen one lobe almost completely disorganised in the course of an illness extending over many months (Case 7). The suppurating tracks are sometimes in the lung itself, sometimes partly in the lung and partly in the pleura. The pus discharged from them has the characters which we are accustomed to associate with liver pus—that is, it is inodorous, thick, slimy, and chocolate-coloured, and may contain the amœba coli, so that I am inclined to believe that the peculiarity of the process depends upon the presence of this parasite. In these cases hæmorrhage is a common symptom; it is often frequent and severe and occasionally is fatal (Case 8). The continued discharge of what has been recognised as liver pus has led to the assumption that the abscess of the liver is still unhealed; but this is certainly not always the case, for I have met with an instance in which the patient, a young man from an unhealthy Indian tea-garden, died from hæmorrhage and at the post-mortem examination so little trace of the liver abscess remained that the medical man who made the necropsy stated that there never had been an abscess of the liver at all. This, however, I knew to be incorrect, for I had had my finger in the patient's liver, and the observation did not surprise me for I have been struck with the complete way in which all traces of a liver abscess even of large size may disappear (Case 7). This is surely a not unimportant fact in making a prognosis, and it accounts for the completeness of the cure if recovery takes place. It is also interesting to note that if an abscess forms in the left lung, as a result of the inspiration of matter from the opposite side, the pus formed in it may be slimy and chocolate-coloured like that which came from the original abscess (Case 9). I do not mean to say that chocolate-coloured pus may not come from a primary abscess of the lung; it may do so, but physicians will agree that this is a most exceptional occurrence. *It may be safely stated that the persistent discharge of chocolate-coloured pus does not prove that the liver abscess is not healed.*

Another danger to which a patient with an imperfectly drained abscess of the lung is exposed is abscess of the brain. I have met with two such cases following tropical abscess (Cases 9 and 10). In one I opened the abscess myself and in the other I directed the operation; both ended fatally.

The practical deduction from what has been stated is that *pulmonary abscess consequent on hepatic abscess should be opened without delay*, and that a careful search should be made for outlying suppurating tracks; that these should be drained by the insertion of full-sized tubes, and, as far as possible, laid freely open even if this should necessitate extensive removal of ribs; and, finally, that the tubes should not be removed or shortened until the surgeon is satisfied that closure of the abscess is almost complete.

Dr. Manson, with whom I have been associated in several of the cases that have come under my care during recent years, has shown that in the majority the amœba coli is present in the pus. In some its presence is more easily demonstrated a few days after the abscess is opened than on the day of operation. In some it is found in abundance many weeks later, when the case is perhaps pursuing a normal course towards recovery. There is, therefore, strong suspicion that the amœba has something to do with the causation of tropical abscess. This persistence of the organism and the very slight effect which it may under some circumstances produce possibly account for one of the most striking features of this disease—its occasional extreme chronicity. One cannot fail to be struck with the long periods of time during which an abscess may be latent, with the way in which symptoms that point strongly to the existence of an abscess may disappear, and with the comparatively slight disturbance of health that is not inconsistent with the presence of an abscess. I have known a young officer who was suspected of having an abscess go go through a winter's hunting and return to show himself, as he thought, well, though the abscess was almost pointing at the epigastrium, and it is well known that an abscess may show itself years after a patient has returned from the tropics.

Some abscesses, on the other hand, after a long period of latency suddenly become acutely septic. These cases most likely become infected from some part of the intestinal tract with the bacterium coli commune or some other septic organisms.

I had under my care last year a young officer invalided home from India on account of liver abscess, but his symptoms so completely disappeared that he was supposed to be well and was sent abroad to recruit. He had, however, occasional attacks of acute epigastric pain, in one of which a swelling formed at the epigastrium which was caused by the rupture of the abscess in this situation. This was accompanied by great collapse and was quickly followed by double parotid bubo. The abscess and the two parotid buboes were opened but the patient died in a few days with all the symptoms of acute septicæmia.

Some liver abscesses contracted in the tropics are, on the other hand, acute and septic from the first. These should, I think, be placed in a class by themselves and are not, properly speaking, examples of tropical abscess but are part of a general pyæmic process. They may arise in this country. They are often multiple and, as far as my experience goes, are quite hopeless cases to treat. But some genuine tropical abscesses are very acute. I saw lately a young man from Central Africa who had had many attacks of fever but no hepatic symptoms till he reached Europe on leave. In the course of a few weeks he developed a small abscess in the right lobe. It was easily reached and it healed in a shorter space of time than any other case I have had to treat, a very few weeks sufficing for the cure.

The majority of tropical abscesses that I have seen have been single and I believe that many of the cases which have been reported of a second abscess following the first are those in which the drainage-tube has been removed too soon or in which a diverticulum of the original abscess has never been properly drained and has been shut off from the main cavity. I think it is of great importance at the time of the operation to explore the cavity very carefully with the finger and to open up all branches of it, as far as possible, before the drainage-tube is inserted. I am, of course, not likely to forget that the cases which we see in England have been sent home from distant parts of the world, and am prepared to hear that others of a totally different type may be met with by surgeons who are on the spot where the disease originates. I have, indeed, been frequently told that we in England do not see the really bad cases, which may be true, though it must be owned that some of them are bad enough in all conscience.

The last point I would deal with is the question of the *best place to make the incision* and will begin by stating that I consider that, if possible, the seat of election for the operation is in the lower axilla. If two lines be drawn vertically downwards, prolonging the anterior and posterior folds of the axilla as far as the margin of the ribs, they will at the lower part inclose the space where the widest interval intervenes between the lowest part of the pleura and the costal margin, an interval generally of two inches and often even greater. The incision may conveniently be made transversely—that is, parallel with the lower margin of the pleura—and the portion of one rib and cartilage that crosses the wound obliquely should be removed, great care being taken to separate the structures on the deep surface of it without injuring the pleura in case by chance it should extend lower than usual. Generally the structure thus exposed consists only of the origin of the diaphragm, but if the pleura should be low it is easily recognised and may without any difficulty be dissected up without injuring it and fastened out of the way to the upper part of the wound. If it should accidentally have

TABLE I.—*Showing the Nature and Amount of the Chief Changes effected between December, 1895, and December, 1901.*

—		For the year 1895.	In December, 1901.

Filters	Number of beds.	—	18
	Area in acres ...	15	22½

In spite of the alterations and improvements which have been effected the water supplied by the West Middlesex Company compares unfavourably with that distributed by the New River Company and the Kent Company. This fact will be seen readily by a study of Table II. which shows the results of analysis of the water supplied by these companies during every month of the year 1901 and during the month of January, 1902. It is much to be regretted that a larger number of complete analyses are not available, but the constant superiority of the water supplied by the deep wells of the Kent Company is beyond doubt.

At the present time, however, the customers of the West Middlesex Company are in many respects at a great advantage compared with those of some of the other companies. The water rents charged are not high. The arrangements for the distribution of water are superior to those of many of the other businesses. The shareholders of the company now receive their full dividends and any increase in the profits of the company becomes practically the property of the water consumers. For their protection, therefore, all that they require is control over the company's financial affairs. This was advocated by Lord Avebury before the Llandaff Commission.

A question which the water consumers should be allowed to decide is whether their profits should be spent in improvements or for the lessening of the water rent. If they were wise they would prefer the former course.

Looking Back.[1]

FROM

THE LANCET, *SATURDAY, APRIL 3*, 1824.

Extraordinary Case of Loss of the faculty of Speech, successfully treated by FREDERICK BASSET, *Esq. Member of the Royal College of Surgeons in London.*

To the Editor of The Lancet.

SIR,—On Thursday the 5th of this month[2] I was requested to see a young lady, eighteen years of age, and a full plethoric habit of body, who had lost her voice in June last; upon enquiry I found, that at that time, from excessive grief and anxiety, she had had a paralytic stroke, which deprived her for some hours of the use of her right side; a medical gentleman was sent for, who attended her for some time, and restored to her the use of her limbs, but not of the organs of speech. She was then removed into the country, where also she was regularly attended by a professional man, and Dr. BABINGTON, there also saw her, and decided the case to be a complete paralysis of the tongue, and I believe was the one who advised galvanism, which was several times performed by Mr LABANMA of Southampton Street, without producing any beneficial effect. It was some time subsequent to this that I saw the patient, and upon examination found Dr. BABINGTON's opinion of the disease perfectly correct, and that the paralysis extended to the muscles of the larynx. The tongue was drawn to the posterior part of the mouth, appeared very white, and with a very feeble circulation through it, quite insensible to the prick of a needle, and perfectly immovable.

I ordered a mustard poultice to be applied to her throat every night, to inhale the steam arising from boiling water, having some flour of mustard in it*; to take one pill composed of extract. colocynth. c. gr. v. & hyd. submur. gr j. every other night, and to gargle the throat and mouth with the following mixture, five or six times a day:

℞ Infus. sinapis, ℥ viij.
Tinctur capsici
——— Myrrhæ aa ℥ j. ft. gargar.

She began this treatment on the day following (Friday) and I saw her again on the Monday after. She was the same, except the tongue looked a little more vascular. I altered the gargle as regards the infus. sinapis to the infus armoraciæ compos,* and desired her to continue the same plan with this exception. On the next Thursday I again visited her, when I found the tongue much more red, and appeared to have every now and then a tremulous motion I ordered her to continue as before, and on the following Monday, when I called, was both surprised and delighted to be accosted by her with "Good morning to you." Upon requesting to know when and how this change took place, I was informed that on the morning after I saw her, she awoke and found her tongue hanging out of her mouth, upon rubbing it she felt it give her pain, and upon attempting to speak, found she was capable of doing so nearly as well as before the attack.

This young lady is now perfectly well, and articulates better than ever, having lost an impediment which had existed from her infancy

FREDERICK BASSET.

* Four or five times in the course of the day.

* I forgot to mention I ordered her some lozenges, made as subscribed, and to dissolve four or five in her mouth in the course of the day—

℞ Pulv capsici, ʒ iij.
Zingiberis ʒ ij.
G Acaciæ ʒ ij.
Sacchari ℥ i et
Esprit de Rose ʒ j.
fiant Troches lx.

[1] It will be noted that the day of publication is now changed from Sunday to Saturday.—ED. L.

[2] Probably Thursday, March 4th, 1824.

been opened the suture of the opening is a simple matter and it is essential to make it perfectly air-tight before proceeding The rest of the operation consists in incising the diaphragm, either in the direction of its fibres or across them (I prefer the former method), and then cutting through the diaphragmatic peritoneum. If there be no adhesions the liver may either be sutured to the diaphragm and the chest walls or the parts around the opening may be carefully plugged with some antiseptic material. If the latter course be adopted it must not be forgotten that if the abscess be large the liver will at once shift its position and that this shifting will take place in the upward direction

It may be asked, "Why lay down this dogmatic rule when it is well known that the abscess may occur in any part of the liver?" But to this it may be answered that, in my experience at all events, by far the majority of abscesses occur in the right lobe, and that if they be of large size they can generally be opened in this situation even if they form a projection in the epigastrium or most nearly approach the surface behind. I have already referred to the difficulties and dangers of incising the liver behind, depending upon the fact that it is necessarily a transpleural operation. The epigastric incision does not drain well and I am therefore in the habit, even if the abscess appears to be pointing in this situation of ascertaining to begin with whether or no the matter can be reached at a moderate distance from the side. It is a question whether, if this be found to be the case, and after making the lateral incision the epigastric tumour disappears, the surgeon should be content or whether he should make an epigastric incision as well A case recently under my care and referred to in an earlier part of this paper supplies an argument in favour of the latter course. I had been content with the single incision in the side, but it turned out that the epigastric swelling had been caused by a localised peritoneal collection of matter due to the bursting of the abscess in front. The communication was not, however, sufficiently free to allow of satisfactory drainage and it was necessary to make the anterior opening in the course of a few days.

I do not deny that the epigastric incision is the only possible one in certain abscesses in the right lobe and in all of those that occur in the left lobe I would strongly deprecate a lateral incision below the costal margin, because the opening is certain to become troublesomely oblique in the course of a few days as the liver shrinks up under the ribs The opening into the liver itself may conveniently be made with a long pair of dressing forceps followed by the finger In this way abscesses at a great distance from the surface may be safely reached and effectually drained Hæmorrhage is often free but it usually stops spontaneously if the finger be retained for a minute or two in the wound. Should it not do so careful plugging round the tube must be practised. Some cases bleed extensively after the operation and the bleeding occurs on subsequent occasions. I am not referring to the slight hæmorrhages which often occur for many days in cases which are pursuing a normal course, but to those in which the loss is considerable. I look upon this as a grave sign and I think it occurs most in the septic as opposed to what I have called the amœbic abscesses. A certain amount of blood often escapes into the peritoneum as the result of the preliminary puncture. It seldom is of any moment, but dangerous and even fatal cases of exploratory puncture have been recorded. It is not unlikely that these patients are either jaundiced or suffering from leucocythæmia

I cannot conclude without referring to Dr Manson's ingenious device of introducing a drainage-tube through a large trocar plunged boldly through all the superficial tissues into the abscess It has yielded excellent results in the hands of many and I would not say a word against it But for my own part I prefer to know in what condition I have left the pleura and peritoneum, and to have ascertained what the size and shape and possible ramifications of the abscess may be, to have opened these up if it appears to be necessary to do so, and to have placed the tube or tubes in what seems to be the best position for the future draining of the cavity

ILLUSTRATIVE CASES.

CASE 1. *Escape of all the bile through the incision made into the abscess, death* —This case was under the care of Dr Manson and has been published by him in the Medical Reports of the Imperial Chinese Maritime Customs, *circa* 1884 The patient was a man, aged about 34 years a tea taster, resident 15 years in China, chiefly at Amoy 10 years previously he had had pleurisy and suffered from stricture and chronic sores on the legs. For the previous four or five years he had had chronic dysentery and had been of intemperate habits. Liver symptoms began in February 1883 There were pain, fever, and other symptoms of hepatitis By August the liver had enlarged considerably and some friction was heard. On Sept. 14th he reluctantly consented to an exploration and pus, which was found at a depth of two or three inches in large quantity of a dark chocolate-brown colour, escaped freely through the cannula which had been introduced A drainage tube was passed through the cannula eight inches long and through this the residual pus was from time to time removed by aspiration Bile in small quantities appeared in the pus and by the beginning of October it was large in amount. On the 13th there was an extensive hæmorrhage On the 16th the abscess was irrigated with a solution of salicylic acid and some sloughy material escaped On the 19th the bile was discharged in very great quantity and on the 30th it all came through the wound and the stools became white. About the same time some thick sloughs came away After this the bile was collected in a bottle and the daily amount varied from 28 to 35 ounces His weight diminished but the appetite remained good. On Dec. 22nd the tube was plugged but this was followed by a rise in temperature so the plug was removed. On the 24th, 25th, and 26th there was bile in the stools. He was then sent on a voyage to America, but on the way he died on Jan. 29th, 1884 apparently from exhaustion owing to the very rough weather, but it was noted that the amount of bile was reduced to 14 ounces per diem and that the stools were coloured so that it is probable that he would, like the patient in the following case, have recovered if he had not experienced such a tossing upon his voyage.

CASE 2. *Escape of all the bile through the incision made into the abscess, recovery* —The patient was a man, aged 48 years, under the care of Sir W H Bennett, who has kindly furnished these notes. He had lived in India since the age of three years. He was well until October, 1898 when he began to have occasional attacks of acute diarrhœa and severe malarial fever In May, 1899, he came under observation suffering from an abscess in the right lobe of the liver which was opened below the end of the eleventh rib at which spot the abscess was bulging on May 22nd. Nothing peculiar was noticed at the operation, but seven hours afterwards the dressings were thoroughly soaked through with pure bile, which continued to flow intermittently The stools were generally white but sometimes piebald, and they partially regained their normal colour during the occasional stoppage of the leakage Dyspepsia was troublesome. There was often great constipation and sometimes diarrhœa. Emaciation was extreme The wound was open from May 22nd to Dec. 26th when permanent closure occurred. Leakage stopped suddenly twice after gradually diminishing to a certain point. The first stoppage of leakage occurred on Sept 28th and no bile was seen for a week Then a profuse flow began suddenly During the cessation of leakage the stools became more normal in colour but they whitened again with the recurrence of the flow of bile. The patient was more or less jaundiced until about a fortnight before the final healing of the wound.

CASE 3. *Rupture into the pleura, very rapid effusion* —The patient was a man aged about 25 years a Ceylon tea-planter, under the care of Dr Bramwell of Cheltenham. He had had hepatic symptoms dating from August, 1895 They subsided and it was thought that the abscess had disappeared but symptoms reappeared in the spring of 1896. The only physical sign observed was a slight elevation of dulness in front. It was intended that I should see him on April 26th but on April 23rd the abscess burst into the pleura during the night On the morning of the 24th the right side was dull all over and the patient was very ill indeed. In the afternoon I saw him and first aspirated two pints of sticky material resembling pea soup and then, without removing any rib let out a further large quantity by an incision on the seventh interspace in the axilla. I did not think that he could stand a more severe operation He died in a day or two and a second abscess was found which was apparently about to burst into the peritoneum The position of it was not stated

CASE 4 *Pulmonary abscess in the anterior part of the lung* —The patient was a lady aged about 30 years who had been in India and who was seen with Sir Richard Douglas Powell This is one of the very few cases of tropical abscess which I have met with in women. The patient developed an abscess in the right lobe of the liver which burst into the lung and which I opened by means of a lateral incision in July, 1896. The fever did not completely subside and there were signs of right pleurisy, but exploration with the aspirator revealed nothing. The expectoration continued. She left for the country with the wound unhealed and by November, 1896, it was obvious that there was an abscess in the lung to the right of the sternum, about opposite the fifth rib. This was opened and drained. The expectoration stopped and both wounds finally healed soundly. The patient has remained well since.

CASE 5. *Pulmonary abscess in the base of the lung behind.*—Dr. S——, aged 35 years, I.M.S., China and India. He had had dysentery and hepatitis in 1894 and was invalided home in September, 1894. He had one rigor in October, 1894, and right pleurisy lasting one month followed by normal temperature for a fortnight. The abscess burst into the lung in December, 1894. I saw him in January, 1895. The physical signs indicated a liver of normal size and a pulmonary abscess behind. The expectoration was about six ounces of blood-stained muco-pus per diem. The pulmonary abscess was opened on Jan. 31st, 1895. The expectoration stopped 36 hours after operation. The abscess was healed completely in three weeks.

CASE 6 *Abscess in the left lung.*—Lieutenant ——, aged 28 years, was sent to me by Dr. John Anderson. He had been in India from 1892 to 1899. He had had no fever or dysentery. Hepatic symptoms began in May, 1899. An operation was performed but no pus was found. Expectoration of blood and pus began in July, 1899, after a fall. He was invalided home in November, 1899. Left empyema was diagnosed. An operation was performed, resulting in the discovery of some clear fluid in the left pleura and the absence of an abscess beneath the left side of the diaphragm. On a subsequent occasion the right pleura and the subdiaphragmatic region were explored and were found to be healthy. I first saw the patient on March 17th, 1900. The physical signs pointed to an abscess in the base of the left lung, behind and inside and below the angle of the scapula. There was no marked enlargement of the liver. There was copious expectoration of reddish-brown pus. The expectoration occasionally stopped, which always caused a rise of temperature. I opened the abscess in the situation indicated by the physical signs—namely, higher up than the previous incision into the left pleura—removing a piece of the eighth rib. The abscess was in the lung, it had thick walls and many prolongations No communication was found with the liver. His general health at once became quite good, but healing was, as might have been expected, slow, the wound not being completely closed till November, 1900.

CASE 7. *Extensive and fatal destruction of lung.*—The patient was a man aged 46 years. When first seen in June, 1897, by Dr. Hector W. G. Mackenzie he had been 22 years in India. In 1890 he had malarial fever. In 1892 he had typhoid fever and was afterwards invalided home. There was no history of dysentery. In February, 1897, he was quite suddenly attacked with diarrhœa and he temporarily lost power over the sphincter ani. He had pain over the ribs on the right side at the same time. He went up to the hills for a time and while there was very ill with fever every night and rigors. Then a purulent discharge from the rectum came on. He returned to Calcutta and an abscess of the rectum was diagnosed; he was relieved by hot hip-baths but was very ill and he lost flesh and strength. The pain in the side continued and in March a severe dry cough came on. In April he began to expectorate pus stained with blood and continued to do so more or less till the end of the case. He was sent to England. Cough, sweating, pyrexia, and depression of spirits continued on his voyage home. When examined by us there were signs of enlargement of the liver upwards in front (level of the third rib) but no increase of liver dulness downwards. The rectum appeared to be healthy. On July 8th a large abscess was opened anteriorly and laterally and this was followed by a gradual improvement in health; but drainage was never satisfactory and there were occasionally attacks of increased cough and expectoration owing to retention of discharge. On Dec. 6th the ramifications of the abscess, which were now found distinctly to involve the pleura, were very thoroughly opened up. During the year 1898 there were periods of improvement and relapse. At one time it looked as if he would make a good recovery; but at the end of the year the tendency was gradually downhill and his condition became more obviously septic. On March 27th, 1899, though he was then very ill indeed, a further attempt at opening up the suppurating tracks was made. They were found to be very extensive, reaching up almost to the apex of the lung. The cavities were bounded in part by the chest walls, in part by broken-down lung tissue. A great portion of the anterior aspect of the right lung had been destroyed by the suppurating process. He only survived this operation a few days. There was no post-mortem examination.

CASE 8. *Destruction of lung; fatal hæmoptysis.*—The patient was a man, aged 26 years, a tea-planter, who was born in India, was educated in England, and who returned to India in 1886 and stayed there till 1893, and had had some attacks of fever. He had dysentery in March, 1893, and was in hospital in Calcutta. The dysentery was not quite cured and he was invalided home in November, 1893, in a very bad state. The dysentery stopped on the voyage and on arrival home he was well except for a dry cough. On Dec. 13th he began to spit blood and matter. On Feb. 20th, 1894, he came under my care. He had lost three stones in weight, and had constant cough, copious chocolate-coloured expectoration, hectic temperature, diarrhœa with blood and mucus, pain in defecation, and difficulty in micturition. His appetite was good; he was given a milk diet. The physical signs indicated great enlargement of the liver and an abscess at the base of the right lung. An operation was performed on Feb. 21st. An abscess in the lung was opened behind and a finger was passed through the diaphragm into the liver. Considerable improvement followed but there were frequent hæmoptyses. Fatal hæmoptysis occurred on April 24th, 1894. Post-mortem the liver was found to be firmly adherent to the diaphragm at the upper part but there was no sign of an abscess. The right lung was firmly adherent to the diaphragm and to the chest wall up to the level of the eighth rib. A large irregular cavity occupied the lower and middle lobes and there was a cavity as large as a Tangerine orange at the right apex. The liver and kidneys were amyloid.

CASE 9. *Abscesses in both lungs and in the brain.*—The patient, a man, aged 43 years, had lived in India for 10 years. He had dysentery soon after his arrival, from which he completely recovered. 16 months before his admission to hospital he had had symptoms of abscess of the liver. Five months later it burst into the lung and four months after that he was operated upon, portions of the seventh rib in the axilla and eighth and ninth ribs behind having been excised. This had not relieved the patient; it was uncertain if pus was found. On admission there were no signs of enlargement of the liver. The physical signs pointed to the existence of an abscess at the base of the right lung. Exploration, however, failed to detect the presence of pus. Three days after operation symptoms of cerebral abscess commenced. Eight days later an abscess was opened in the right occipital lobe, the only localising sign being tenderness on percussion. On the same occasion an abscess in the base of the right lung was opened through the old scar in the axilla, more space being gained by removal of more portions of ribs. No improvement followed and another trephine opening was made in the hopes of finding a second abscess in the brain, but none was discovered and the patient died 20 days after the first operation. At the post-mortem examination the lower lobe of the right lung was fibrotic and riddled with cavities. The right pleural cavity was obliterated at the base. The left lung contained a cavity as large as an orange opposite to the fifth, sixth, and seventh ribs, and the pleura in this situation was obliterated. The brain contained a large abscess in the right occipital lobe but there were no other collections of pus. There was little or nothing to indicate the old abscess in the liver.

CASE 10. *Abscesses in the lung and the brain.*—The patient was a man, aged 33 years, a merchant, and was seen with Dr. Crombie on Jan. 9th, 1901. He had lived in Calcutta for seven years. He had had very little fever. In May, 1897, he had dysentery and congestion of the liver which lasted till the end of the year He was invalided home on account of sprue in January, 1898, and remained till September of the same year. Liver symptoms began in September, 1899. Pus was removed by aspiration in October. Aspiration was again performed in November but nothing was found. In January, 1900, cough began and had continued ever since He had had intervals from fever and cough lasting a week but not longer. These were followed by a rise of temperature and expectoration. He had lost some flesh but not much. In June, 1901, he had signs of a pulmonary abscess at the right base which was opened by a posterior incision opposite the eighth rib. There was a gradual improvement, though drainage was never perfect because the cavity had many branches and a considerable amount of bright blood and pus was discharged from the wound and expectorated as well. He improved so much, however, that he was sent to Christchurch, Hants, under the care of Dr. Leslie B Burnett. In September symptoms of cerebral abscess manifested themselves and before long symptoms pointing to affection of the left motor area appeared. Dr. Burnett explored this region but found no pus. A few days later, at my suggestion, he explored further back and found a considerable abscess in the left occipital lobe. There was some improvement but the patient died on August 3rd Post mortem the right lobe of the liver was found to be adherent to the diaphragm but it contained no pus (compare Case 8); the abscess in the lung was extensive and it branched out into numerous pockets; part of its wall was formed by the ribs (compare Case 7) A considerable cavity existed just beyond the end of the drainage-tube The abscess in the occipital lobe was not empty, an accumulation existing beyond the end of the drainage-tube

IS CHLOROFORM MORE DANGEROUS THAN ETHER?

CONSIDERATION OF RESPIRATORY TROUBLES FOLLOWING OPERATION DURING 12 MONTHS AT A LARGE GENERAL HOSPITAL.

BY H. CHALLICE CROUCH, M R.C.S ENG., L.R.C P LOND.,
ANÆSTHETIST TO ST THOMAS'S HOSPITAL

AND

EDRED M. CORNER, M.B., B.C. CANTAB., F.R.C.S ENG.,
RESIDENT ASSISTANT SURGEON, ST THOMAS'S HOSPITAL.

DURING the session 1899-1900 there took place at the Society of Anæsthetists a discussion on the After-Effects of Ether Inhalation on the Respiratory System.[1] The discussion was carried on by a large number of members and visitors, all, or at any rate a majority, of whom were experienced in that particular branch of the profession. As the meeting proceeded it became increasingly evident that not only was there no general consensus of opinion as to the cause and prevention of such respiratory affections after ether, but it was even denied by some that such complications existed at all, and the climax was reached, as was only right and proper, when the President, Dr. J F W. Silk, in the last words of the last speech, said that "he was almost inclined to think with Mr Carter Braine that the inhalation of ether was, if anything, protective against pneumonia."[2] As there was, however, and always has been, a very strong opinion among medical men generally that such complications did arise after ether it occurred to us that the matter required further examination; we therefore determined for a space of 12 months to watch every in-patient in St. Thomas's Hospital who had had ether or chloroform administered to him and see in what proportions these respiratory complications did arise.

For such a series of observations to be accurate and satisfactory they must be undertaken by one who is not only in a position, but is forced by routine, to examine every patient from the date of operation to the date of convalescence or death The observation, moreover, must be undertaken by the same man over the whole period Such an observer is, as a rule, difficult to discover in a large hospital, and it must be a large hospital, otherwise the number of patients would be too small to be of value, but at St. Thomas's Hospital in the surgical registrar we have such an officer with the necessary qualifications and that share of the work has been done by him.

We had at the outset made up our minds that we would include in our list no cases of "ether inflammation" (by this we mean any respiratory complication following the administration of ether) which did not arise within 24 hours. We were quite aware that many observers, both at home and on the continent, had given it as their opinion that respiratory troubles arising even as late as three weeks after the inhalation] might be due to the latter. We, however, bearing in mind Dr. Dudley Buxton's remarks on this point, foresaw that unless we fixed a narrow time-limit it would be pointed out, and rightly, how a number of other factors would come into play which would lead a large number of our cases to be rejected.[3] In order still further to disarm criticism we abstained from adding to our list any case in which the temperature may have been influenced by suppuration. Cases did occur of fever with respiratory complications which we were satisfied were true cases of "ether inflammation," but as there was more than stitch-hole suppuration we felt that they were "not proven" and rejected them. One case (No. 9 on the list) would seem at first to have contravened this rule, but in reality it did not do so, as the sloughing of the flap and the subsequent suppuration started after the bronchitis had stopped. The same rule applied to patients who might have had influenza or tubercle.

It will be as well here to state the conditions under which patients are operated on at St. Thomas's Hospital. The anæsthetic is administered either by the staff anæsthetist or by a student under his direction or by one of the house officers The operation is performed in nearly all cases in one of the large theatres. The anæsthetics employed are either gas and ether or chloroform. The only mixture that is used is A.C.E. and this hardly ever. One of the staff (Dr. E. H. Grant Morris) we believe very occasionally uses equal parts of chloroform and ether for children, and Mr W. Tyrrell, President of the Society of Anæsthetists, also very occasionally gives a demonstration of his "two bottle method." The exceptions, indeed, to the administration of ether with gas or chloroform alone are very few. The mask used for chloroform is a wire frame, covered with lint, the lint being renewed for each patient. The apparatus employed for ether is Clover's portable inhaler with a bag made of red rubber which is boiled after each case and with a facepiece that is carefully washed. The gas is administered through a Barth valve, the bag being a four gallon one. No wet towels are used at all during the operation, the patient being covered with towels which are dry after being sterilised in tins surrounded by superheated steam. After the operation the patient is carried in a trolley along a corridor to the ward. Where the ward is above the level of the corridor he is also taken in a lift. The remaining patients—cases mainly of fractures requiring setting and of cellulites requiring incisions—are operated on in small theatres opening directly out of the wards, the anæsthetic here being invariably administered by a house officer The locale and the type of operation are not the only differences. A very large number of these cases are chronic drinkers, some, indeed, suffering from alcoholic poisoning at the time of the anæsthetic, and many, owing to their septic condition, are much enfeebled. They are all operated on within a few hours of admission and therefore undergo no preparation, and finally—a matter of much importance—the ether is nearly always given without the previous administration of gas.

During the 12 months under consideration (the year 1900) there were given in the hospital just over 3000 anæsthetics, both chloroform and ether The figures cannot be exact, as a certain number of casualty cases had more than one anæsthetic, the second being for purposes of readjustment of splint, &c. We do not think, however, that the error would be 20 one way or the other 2842 of these were given in the principal theatre, the remainder in the smaller theatres adjoining the wards. The accompanying table contains details of 10 cases of respiratory complications undoubtedly due to the anæsthetic. All of these cases occurred with ether, not one with chloroform. It only remains now to analyse these cases and to see whether there is a common cause to account for the lung trouble.

1. *The age of the patient*.—From this there is nothing to be learnt, the trouble arose at all ages. There was a case in a child, aged nine years, below which age ether is but rarely given, and another in a woman, aged 64 years, who had practically reached the upper age limit for ether.

2. *Previous lung condition*.—The history was uniformly good if we may except two previous attacks of pleurisy, one of which occurred 20 years before In one case the patient had a cough but there were no physical signs What is

Table of Respiratory Complications following the Administration of Ether at St. Thomas's Hospital, 1900.

No.	Date.	Sex and age (years).	Previous chest condition	Operation	Temperature 24 hours afterwards.	Nature of respiratory complication.	Duration of respiratory complication.	Condition of wound.	Remarks.
1	Feb. 5th.	M, 62	Pleurisy 20 years previously	Colotomy for carcinoma of the rectum	101·4° F.	Bronchitis.	12 days temperature over 101°; normal on the fourteenth day.	First intention.	No difficulty with anæsthetic.
2	March 31st	F, 34	Good, but cough before going to theatre. No physical signs.	Whitehead's operation for hæmorrhoids	101·0°	Broncho-pneumonia Consolidation of the left lower lobe of the lung. Mitral stenosis on the seventh day.	Temperature normal on the fourteenth day.	"	"
3	May 16th	M, 56	Good	Inguinal hernia. Undescended testis Bassini's operation	101·4°	Bronchitis; not severe.	Temperature normal on the eighth day.	"	"
4	" 29th.	M 9	"	Inguinal hernia Undescended testis. Bassini's operation	103·0°	Broncho-pneumonia Report on the third day: dulness over the lower half of the left lung posteriorly, and air entry poor, occasional tubular breathing and crepitation, probably diffuse broncho-pneumonia, with possibly some fluid at the base.	Temperature normal on the seventh day.	"	"
5	July 9th	M, 34	No respiratory trouble.	Pyonephrosis, nephrectomy.	101·0°	Bronchitis, broncho-pneumonia, pleurisy.	Death.	—	No difficulty. Full account of case in text.
6	" 10th.	M., 15	Good.	Radical cure of inguinal hernia; Bassini's operation.	103·5°	Bronchitis.	Temperature normal on the fifth day.	First intention.	No difficulty.
7	" 27th	M, 19	No trouble in the past	Radical cure of inguinal hernia, Bassini's operation	102·0°	Bronchitis and pleurisy. Report on the fourteenth day aspirated two and a half ounces of fluid drawn off. Asp'ration had been advised on the tenth day.	Temperature normal after aspiration.	"	"
8	Sept. 6th	M, 23	Good	Varicose veins (extensive).	101·6°	Bronchitis definite but slight.	Temperature normal after the fourth day.	Wound was dressed on the eighth day; slight suppuration at two incisions.	"
9	" 12th	F, 56	"	Amputation of the breast and axillary glands.	103·6°	Bronchitis and cough.	Temperature normal after the eighth day.	Piece of flap sloughed, followed by suppuration.	No difficulty. Sloughing occurred after bronchitis had ceased.
10	Nov 19th	F, 36	Previous attack of pleurisy.	Amputation of the breast and axillary glands and above the clavicle.	102·0°	Bronchitis and sputum.	Temperature remained up for some time.	Slight suppuration in both wounds.	No difficulty. In this case there was a definite dry stage with pain at the sternum and dry cough.

more remarkable still is that where ether was given to patients with chronic bronchitis no untoward symptom arose. The cases of two patients, indeed, are worth mentioning. They were females, aged 65 and 39 years, suffering from irreducible femoral and ventral herniæ respectively. They both had an extremely well-marked history of winter cough, and, more than that, had cough with expectoration at the time of operation. They were given ether and were none the worse for it.

3 *Condition of patient at the time of operation.*—In all cases the condition was good. It has been suggested that the occurrence of respiratory complications after ether could be explained by the routine use of that anæsthetic in the cases of patients in a desperate condition. This has certainly not been our experience. There was, however, one case which would appear to support this view. The patient was a woman, aged 57 years, in bad condition, suffering apparently from carcinoma of the liver; ether was administered for an exploratory operation. Before an incision was made the woman became blue and [illegible] pulse extremely feeble. On auscultation the lungs [illegible] of bubbling sounds. She was taken back to the wards and died in five minutes. Post mortem the lungs were found to be extremely œdematous; there were no signs of bronchitis. We have not included this case, as we felt that such a condition is sometimes due to a dying heart. The same condition has, however, been said before now to be due to the directly irritating effect of the ether. We have quite an open mind on the subject and would particularly wish for opinions on this case.

4 *The operation.*—They were all trunk cases except on which was a very extensive case of varicose veins, the operation lasting nearly two hours. They were all long cases. The "colotomy" included a long examination, the herniæ were all "Bassini's" operation for radical cure, while the breast cases had extensive gland infiltration.

5 *Behaviour of patient during anæsthesia.*—The vari anæsthetists reported, when questioned on this point, difficulty of any kind, no particular tendency to cyanosis excessive secretion, neither did the patients require abnormal amount of ether.

6 *Time of year.*—Seven out of the 10 cases occurred in summer; it is certainly a question whether at that tim

year the patients, owing to freer ventilation, are not exposed to greater draughts.

7. *Locale*.—The patients were all operated on in the large theatre and afterwards taken by lifts and corridors to the wards.

8. *Experience of anæsthetists*.—All the anæsthetics were administered by house officers and not by the staff anæsthetists. The former had not naturally the experience of the latter but they could not be called inexperienced.

9. *The anæsthetic employed*.—In all the cases the ether was preceded by gas. We mentioned earlier that the gas-bag was a four-gallon one. We would suggest that owing to this excessive size the patients are given an unnecessarily large amount and the resulting cyanosis has much to answer for.

10. *Conditions after the operation*.—They were all cases that required such bandaging that of necessity the chest and abdominal movements were restricted and their powers of expelling sputum curtailed. A description of the ward, the ordinary large ward of a hospital, is, we imagine, unnecessary.

11. *Healing of wounds*.—Of the wounds of the nine surviving cases six healed by first intention. Two had slight stitch-hole suppuration, while in the remaining case, owing to the extreme tension, a piece of skin-flap sloughed and subsequently suppurated. In none of the three cases was the suppuration of such a character as to account for the temperature.

12. *Character of the respiratory complications*.—In six patients the symptoms and signs were those of bronchitis. In one case (No. 10) there was a definite dry stage lasting for the first 24 hours, characterised by hard cough, pain at the sternum, and very scanty expectoration, exactly as is usually seen in a typical case of acute bronchitis, so making this case appear to be the result of exposure. In the other five cases there was from the very first a copious expectoration. In our seventh case some pleuritic effusion occurred; it was noticed on the tenth day and two and a half ounces of fluid were drawn off on the fourteenth day. Three patients had broncho-pneumonia—one of these died, the symptoms and signs of the other two cleared up within a week, the temperature coming down by lysis. There was no case of true lobar pneumonia.

Fatal case: bronchitis, broncho-pneumonia, pleurisy.—The patient was a male, aged 34 years, suffering from pyonephrosis; nephrectomy was performed on July 9th. There was a calculus in the right ureter. The anæsthetic (ether) was given by an assistant house surgeon who experienced no difficulty in the administration. There was no past history of respiratory trouble. 24 hours after the operation there was cough, and after the operation the temperature, pulse, and respiration were as follow:—

Days.	Temperature.	Pulse	Respiration.
1	101·0° F.	108	26
2	103·4°	124	30
3	102·0°	124	32
4	103·2°	128	38
5	103·2°	124	42
6	103·2°	128	42
7	104·0°	132	44
8	104·2°	148	50
9	104·4°	140	48
10	108·0° at death	—	—

On the fourth day after operation the resident assistant physician, Dr. A. E. Russell, made the following note: "Respirations 52, pulse 132. Dulness at extreme right base and round angle of right scapula, here also breath sounds are tubular. Air is entering to the base of the lung and there is no evidence of emphysema. There is some pneumonic consolidation of the lower lobe, especially of its upper portion." And again on the eighth day: "The left lower lobe now involved; right lower lobe clearing up."

Necropsy.—The trachea and bronchi were much injected and contained some frothy mucus. The bronchial glands were swollen and succulent, not tuberculous. Each pleural sac contained a small quantity of blood-stained serum. There were no adhesions. The lungs were dense and heavy. Each lower lobe was partially collapsed and its investing pleura was wrinkled. Many small broncho-pneumonic patches were present in the lower and middle lobes of the right lung, with one of the size of a filbert in the inner part of the middle lobe. In the left lung the broncho-pneumonia was more extensive than in the right. Both lobes were involved but the areas were small. No abscess or tubercle was seen. The pericardium contained blood-stained serum in small quantity.

To sum up, out of some 2400 patients to whom ether had been given 10 developed temperatures with some respiratory troubles within 24 hours and all of them had inhaled gas previously to the ether. There was no previous history of bronchitis in any case and all were in good condition at the time of operation and took the anæsthetic in a perfectly normal manner. The operations were prolonged ones and with one exception the trunk was the site of operation. On leaving the theatre the patients were taken along corridors and in lifts, the temperature of which would certainly be below the temperature of the theatre, to a ward where they would have to lie for several days in a position which would probably retard, and enveloped in bandages which would certainly prevent, free expectoration.

Though under the same conditions precisely not one of the 600 patients who had chloroform developed any form of respiratory trouble. And in this connexion we would call to mind two cases reported by one of us two years ago.[4] Two patients were operated on for some bowel trouble; they both had ether and both developed ether inflammation within 24 hours. After the lapse of one month and two months respectively they underwent a far longer operation with chloroform without any respiratory complications of any kind. This freedom from respiratory troubles after chloroform is the more remarkable when we consider what a large proportion of these were mouth cases, a class of operations always considered very liable to such a complication. A contrast equally remarkable is seen in the cases of those who were operated on in the small theatres adjoining the wards, none of whom suffered from this complication. Here, it will be remembered, ether is given usually without any previous administration of gas to cases of fractures and cellulites. The period of administration is not very prolonged, but, on the other hand, a large proportion are patients in an enfeebled condition due to alcohol or sepsis; none of them receive any preparation and many of them have to put up with the same drawbacks as regards posture and bandaging as have abdominal cases.

These ward cases, then, differ from those of the large theatre in four ways: (1) the latter invariably have gas administered before the ether while the former usually have ether alone; (2) the latter operations were long and the former were short; (3) the latter were trunk cases and the former for the most part were limb cases; and (4) the latter have to traverse corridors to get back to the ward and the former are operated on in an annexe of the ward. It must be remembered, however, that the ward cases included a large number of fractured thighs which suffered the same drawbacks as regards posture and bandaging after the anæsthetic as the trunk cases.

Such are the facts which we have had to put forward. The figures are remarkable—10 cases of "ether inflammation," one of which proved fatal, out of about 2400 ether inhalations. When this investigation was begun we had no idea that such a state of things existed. We are quite prepared to be told that such a condition does not exist in this or in that hospital and we are equally prepared to decline to accept any such general statement of denial. 12 months ago, had we listened to such a paper, we would have vigorously denied the existence of such a state of things at St. Thomas's Hospital. To-day we are wiser. Unless every case is examined with the same thoroughness that our cases were no one is in a position to put forward a claim to better results. The anæsthetists never hear at all of the subsequent history of their cases; the surgeons are interested in the state of the wounds, leaving the house surgeon, who, as a rule, has not sufficient experience to connect the ether with the cough and temperature, to look after the patient's chest. Thus has been created a condition of false security.

With these figures before us we must reconsider our position with regard to ether which in the present light bids fair to oust chloroform from its place of dishonour. The death-rate from chloroform is usually considered to be 1 in 3000.

---

[4] Transactions of the Society of Anæsthetists, vol. iii., 1900, p. 83. Clinical Journal, August 8th, 1900, p. 253.

Our figures work out for ether at 1 in 2400[5] and are very similar to those of the London Hospital of 1897—1 in 2910—which were mentioned by Dr. Probyn Williams at the debate at the society.[6] If these figures are correct it seems to us that in preaching the greater safety of ether than of chloroform anæsthetists would be acting wrongly. We are merely changing the venue of the death from the operating-table to the bed, the house surgeon's signature for the coroner's. The chief cause of this frequent and, in cases, alarming complication, then, is ether. The contributing causes are the length of the operation, the previous administration of gas, the inexperience of the anæsthetist, and the exposure of the patient during and after the operation.

The remedies are not so obvious. Manifestly we cannot advocate the entire giving up of ether, for, after all, chloroform has troubles of its own. But we do recommend chloroform for all long operations on the trunk. We do not desire to banish the previous administration of gas but it should be so arranged that too much cannot be given by inexperienced anæsthetists and that can be best done by having the gas cylinders away from the anæsthetising-room and the gas bag of moderate dimensions, say two gallons. After the operation the patient should have the mouth and nose carefully protected from the cold air of the corridors and the ward by means of a loosely-folded towel over the face.

In conclusion, we must mention that we are deeply indebted to Dr. Russell, the resident assistant physician of St. Thomas's Hospital, who most kindly examined every case to which his attention was called. Without his assistance we could not have been so certain as we are that we have given only true cases of ether inflammation.

POSTSCRIPT.

At the meeting of the Society of Anæsthetists at which the above paper was read there seemed to be some confusion about the object with which it was brought forward. The question as to whether ether or chloroform is the most dangerous was raised from consideration of their post-operative complications. The evidence brought forward in this communication clearly demonstrated that in this particular chloroform was *facile princeps*. Most of the speakers in the discussion that followed dealt only with the dangers that are run during the administration. We have in consequence decided to add to our paper the cases in which a fatal result took place during the period of anæsthesia. One death occurred under chloroform and was that of a child who was being cleaned up after a burn. From the extent of the burn and the condition of the child, aged one and a quarter years, it was an error of judgment to have attempted such a proceeding at all. An abstract of the case is given in the St. Thomas's Hospital Reports for 1900, p. 181. Obviously it is unjust to put the child's death down to the anæsthetic. With ether we were unfortunate enough to have a death also. This was in the case of an anæmic, fat, elderly man who was suffering from an extensive and exquisitely tender cellulitis of the knee. His heart was flabby and he had albuminuria. Ether was administered in an annexe of the ward, as described above, without the previous use of gas. Some difficulty was experienced and the respirations became shallow, death occurring before the operation was begun. None of the staff anæsthetists were present. The last case is recorded in the St. Thomas's Hospital Reports, 1900, p. 179. It is not fair to either anæsthetic to put these results to their account. In our communication we have recorded one case, and probably a second, in which the fatal result was due to ether, but both these cases happened after the return to the ward and therefore out of sight of the anæsthetist or the surgeon. Our statistics on all points raise the question of the relative dangers of chloroform and ether. In conclusion, we wish especially to draw attention to the advisability of changing the anæsthetic to chloroform after a time, when ether has been given originally. The reasons for this are dealt with by one of us in the *St. Thomas's Hospital Gazette*, 1901. This is not a new procedure and many speakers referred to it as their frequent practice. As the fear of chloroform will deter many from its use and the "operative" safety of ether will keep for it many advocates we strongly recommend this change of anæsthetics.

THE FEEBLE-MINDED AND CRIME.

BY MARY DENDY,

HONORARY SECRETARY OF THE LANCASHIRE AND CHESHIRE SOCIETY FOR THE PERMANENT CARE OF THE FEEBLE-MINDED.

MY object in writing this paper is to call attention to the fact that a large number of philanthropic persons are expending a great amount of time and energy and good feeling and vast sums of money in attempting to do away with evils which are only the symptoms of a widespread and constantly increasing disease. As a result of many years of work amongst the poor, of a minute attention to the condition of children in our public elementary schools and in their own homes, and of a certain amount of reading and of consideration of expert opinion, I have come to the conclusion that the main cause of most of the evils which keep so many of our people in a degraded condition is weakness of intellect. This cause would operate equally in all classes of society but that in the so-called upper classes the feeble-minded are generally guarded from the natural consequences of their defect. Even amongst these, however, the trouble is passed on by marriage, and probably some cases escape notice and account for instances which occur, otherwise incomprehensible, of descent in the social scale. Mr. Holmes, the prison missionary, tells us of one man whose parents were highly respectable, who had no motive for stealing, who was well educated and intelligent generally, but who could not help stealing watches. I know at this moment of a boy, whose father does not belong to the working-classes, who has been twice convicted of stealing; he is abnormally naughty in other ways and his brother is in an idiot asylum but no one recognises the fact that he is not responsible for his actions and he will descend in the scale of life until he is a habitual criminal. Further, weakness of intellect is in the majority of cases an inherited disease and a very large proportion of feeble-minded persons have children, either with or without marriage. There can then be no way of stopping the increase of this disease but by caring for feeble-minded persons during their whole lives.

Hooligans, or corner-lads, criminals, paupers, and drunkards—all are these frequently only because they are feeble-minded. The lying-in wards of our workhouses, idiot asylums, deaf and dumb asylums, special classes, reformatories, and industrial schools, to say nothing of the homes which are springing up everywhere as the result of private charity—all are fed by our feeble-minded population or their offspring (for it must be remembered that the child of the merely feeble in mind may be an idiot), and the managers of these refuges all fail to stem the evils with which they contend because they act on the assumption that temporary care and training are all that are needed. So after a term of years their patients are turned out again on to the world, trained to obey and to behave decently under the strict supervision of their keepers but not trained to stand alone and in many cases only more helpless that they have been kept in leading-strings so long. It needs to be understood that the feeble in mind cannot be trained to stand alone. As the lame man wants his physical crutch, so these poor creatures need their mental crutch and when that is withdrawn they inevitably fall. The more amenable they have been to good influences the more readily will they succumb to bad ones. They lack will-power and this must be superimposed from without; if it be a power for good all is well, if for evil, as it generally is, the result is disastrous.

Two years ago I made an inspection of all the children in actual attendance in the board schools in Manchester with a view to ascertain how many of them were in such a mental condition as to make instruction in special classes necessary for them. At one time there were 494 children in these schools needing such instruction out of a total of 39,600. Of these 494 children 214 were "dull and backward," it being understood that their condition was due to their state of mind and body and not to neglect, 276 were "mentally feeble," and four were deaf-mutes. I need not say that to obtain these results I did not rely upon my own opinion—in every case the child was seen by Dr. H. Ashby of the Pendlebury Children's Hospital. I further saw in their own homes 45 children who were excused from school attendance by medical certificate. A more minute analysis of these two sets of children gives the following results. Of the 494 feeble-minded children attending school, 78 boys and 63 girls were so hopelessly defective that it would be impossible for them, in the most favourable circumstances, ever to reach a normal mental standard. Of these, again, four boys and eight girls were so imbecile that they could be properly placed only in an idiot asylum. Of those excused from school attendance there were 22 boys of this type, of whom 10 were asylum cases, and 11 girls, of whom three were asylum cases. We thus get a total of 100 boys, of whom 14 are asylum cases, and 74 girls, of whom 11 are asylum cases. Thus leaving out of question the milder cases, it is found that amongst the board school children of Manchester there are 174 children who can never be trained to take care of themselves and who must inevitably be a great danger to society. Only about half the children of Manchester attend board schools and there is reason to suppose that similar results would be obtained by an inspection of the other half who are in voluntary schools. Those children who are excused from school attendance were not necessarily worse than those going to school, but their mental or physical peculiarities either made it impossible for them to go safely through the streets or else caused them to be unmanageable in company with other children.

---

[5] Possibly 2 in 2400 if the case recorded above is counted. Also see postscript of fatal cases added to this paper.

[6] Transactions of the Society of Anæsthetists, 1900, p. 101.

Last year I inspected in the same manner all the voluntary schools in a large non-school-board area near Manchester, including Church of England, Congregational, Roman Catholic, Undenominational, Methodist, and British schools. Here, again, the cases which I selected were seen by skilled medical men. We put on our list 150 out of 3000. This larger proportion was accounted for by the fact that one school received scholars from a home for waifs and strays who were all of a very low type.

It appears that there are always about three defective boys to two defective girls. This, I am told, is because all characteristics are more strongly transmitted to males than to females. The law so far recognises the existence of this class of children as to provide in a half-hearted sort of way for their education up to the age of 16 years. I say in a half-hearted sort of way because its permits but does not enforce the provision of special classes for their instruction. It defines them as "children who by reason of mental or physical defect are incapable of receiving proper benefit from the instruction in the ordinary public elementary schools, but are not incapable by reason of such defect of receiving benefit from instruction in such special classes or schools as are in this Act mentioned." The condition of some of these children is accounted for by curable physical disease—such as deafness or bad sight; of others by early neglect and bad home surroundings; of others by illness which has caused them to lose some years of school life. In these cases the extra time at school and the minute attention to their particular requirements given in the special class will suffice to bring them up to the level of the average child. But there are many more in whom the trouble is of a quite different nature and who are no nearer to being cured at the end of their school life than they were at the beginning. It must be remembered that many amongst the milder cases classified in Manchester would be incurable though the disease had not in them assumed its most troublesome form. Given, then, in any town a complete system of special classes, in those classes will be found the raw material for most of our social failures; boys and girls who are recognised as abnormal up to the age of 16 years and who are then discharged to be worked up by the pitiless machinery of our streets into the criminals, paupers, and lunatics who are the insolvable problem to all our philanthropic agencies.

Let us take examples of a few of the very numerous types of feeble-minded children and try to see what becomes of them.

R. is a gentle-tempered, obedient boy, aged 16 years. In his spare time he plays with sticks and stones like a child or at "gee-gee" with his bed posts. He is at work, but it is doubtful if he will keep his situation because he has hurt himself with the machines. He has more than once stolen because he was ordered to do it by bigger boys who took his stolen goods from him. He will never become a "Hooligan" but he is very likely to become a thief or a train-wrecker. Quite recently the police reports contained notices of two boys convicted for attempted train wrecking who were known to be of feeble mind. Older boys were implicated in the same charges with them. Probably R. will become a father.

T. is a lad who can do a certain amount of head-work, though he is behindhand. He is fairly strong physically and will probably be able to maintain himself after a fashion as a labourer. But he is one of that peculiarly difficult class of children who have no moral sense. He is exceedingly mischievous and shortly before I saw him he had procured a box of matches and set fire to the cloaks in the school cloakroom. Little J., again, is another boy of this kind; he is destructive to the last degree and having set his heart on achieving one particular piece of mischief (the pulling down of a piece of lead-piping from a wall) even very severe physical punishment several times inflicted would not keep him from returning to it again and again. Restless and troublesome in class, dangerous in the playground, quite unashamed, untouched by kindness or punishment, these lads will inevitably grow into the Hooligan type. L. is 20 years of age now and earns some sort of a living; he is the terror of all who have to do with him, the son of a father who was "queer," and he is an ill-conditioned, badly-built lad with a malformed head. I think he has not yet been convicted but that is only a question of time. Perhaps he is a degree better than the lad who kicks an unoffending workman to death; many people have tried to keep some hold on him. Probably all these lads will become fathers.

G. is a boy, aged 15 years, an orphan. He attended school regularly but never learned anything. He was taken on at the "shop" where his step-grandfather worked and could do what he was put to, but he was so fascinated by the leather bands going round the wheels that he could not resist the temptation to put bits of rag and string under them to see them drawn into the machinery. He was, of course, discharged. He is now in an idiot asylum and he will be discharged at the end of seven years to take his share in producing the next generation.

It would be easy to multiply cases, but these must suffice for the boys. Briefly speaking, what generally happens to feeble-minded boys of the poorer classes is this. A boy leaves school quite unable to take care of himself. Very often the one wholesome guiding influence of his life ceases with his school days, his parents being frequently only slightly stronger in mind than himself. Their one notion is to make him earn money for them. He knows no skilled work and cannot keep a situation if he gets one.[1] Then he goes upon the streets, sells matches, shoelaces, papers, and generally ends by getting into gaol. By this time he has become used to a vagrant life and as he can only move along the path of the least resistance and as it is made so much easier for him to go wrong than to go right he continues to go wrong and becomes a confirmed criminal. So he grows up through a pitiful and degraded youth to a pitiful and degraded manhood and dies, leaving behind him offspring to carry on the horrible tradition.

The following are some examples of female cases. With the girls the evil is more obvious though not more real. To begin with the moral imbecile.

S. is a girl in a board school in Manchester reported on by Dr. Ashby. She was bright at her lessons, fairly well grown, and pretty. Her father was a criminal who had deserted his wife. Her appearance was normal except for a restless expression in the eyes. She stole in the school very ingeniously, taking garments which she sold for a few pence to buy sweets. When her mother flogged her she slept out and was more than once taken home by the school attendance officer. She was quite without shame—in fact, she gloried in her achievements. When spoken to by a skilled observer it was at once obvious that her mental condition was abnormal. Dr. Ashby said: "If I were to tell a judge and jury that this girl is not responsible for her actions they would laugh at me, but if she is not put under constraint at once she must inevitably join the criminal classes." This girl would become very likely such a one as N., a girl 18 years of age, whom I know and who was living the worst possible kind of life. I could make no impression at all upon her. Her answer to my remonstrances and offers of help was a silly laugh and "the police can't get me for anything I do." She had no conscience beyond half-a-crown and costs. She also was a rather pretty girl and did some work for her living. Going to see her mother I found that the latter was a deaf-mute. Or possibly S. might become a criminal of another type, like poor little M. who was sentenced to 16 years' penal servitude for the manslaughter of her employer's children by drowning them. M. was 15 years old and would be released when she was 30. All these three girls would probably become mothers.

---

[1] Dr. J. Kerr, late of Bradford and now medical adviser to the London School Board, who has given much attention to the children in the special classes there, says it is characteristic of the boys that though they can do some kinds of work and generally find situations when they leave school they never keep their places and are always on the streets.

Fortunately, with the girls as with the boys, the morally defective are not the commonest type of the feeble-minded.

E. is a small delicate child whose mother is a deaf-mute. P., aged 12 years, is in Standard I. She cannot speak clearly, cannot see properly, and cannot carry a message. T. is an overgrown, delicate, defective girl, aged 12 years. These three girls are of a very usual type, nervous, timid, biddable children, just those who are ready to fall a prey to any evilly-disposed person who comes across them. These are the children who to a very large extent account for the child-mothers in the lying-in wards of our workhouse infirmaries. This extract from the *Manchester Evening News* of Feb. 26th, 1900, gives an example of how the trouble comes to pass: "It was stated to the magistrates at the City Police Court this morning that S. T., a girl of nearly 16 years of age, had been missing from her home since Friday morning, when she left home to go to her work but did not turn up. *As she is of rather weak intellect* it is feared she has been decoyed." It is not very long since I saw a child, aged 14 years, in the workhouse infirmary with her infant in her arms and there are few women guardians who could not give several similar instances.

The life of girls such as these is pitiable in the extreme. Year after year they return to the workhouse to bear children, many of whom fortunately die but some of whom live to repeat their mothers' experience. Year after year they become more degraded, wretched, and restless. At the present time there is in a workhouse a feeble-minded boy whose feeble-minded mother has been in and out 21 times during a year. In the same workhouse there have been during the last three years amongst the mothers of illegitimate children 16 who were of weak intellect. Nor do the girls who come under notice in this way represent nearly all of their class; very many are confined at home and it is a marvel that more do not die merely from the hardship of their conditions. In one house to which I went to inquire for a feeble-minded boy I found also his sister, a woman 35 years of age, of weak intellect and deaf, nursing her third illegitimate child.

This disease, moreover, as things are at present is no bar to marriage. I know of a woman, aged 28 years, who was married at 16 years to a notoriously half-witted man. She "did not know he was silly" when she married him. She is very ill and evidently has some serious internal complaint which will soon kill her, when her husband will be at liberty to marry again. She has had 10 children, of whom she has "buried eight," as the phrase goes. The remaining two are feeble-minded, the elder, a girl aged 13 years, in a marked degree. In all probability this child will be a mother before long. Mr. Holmes, from whose book I quoted above, tells me that many children of weak intellect are committed to reformatories, certified as "fit" because the medical man who has had them under observation has seen them only under such control as prevented their mental peculiarities from showing themselves. Frequently when these children have been a little while in their new homes the unfitness becomes manifest and because there is no provision for them under the same roof with sane children (indeed, there hardly could be such provision) they are discharged, to come again upon the streets and again to be convicted. In this way he has known the same boy to be twice committed to a reformatory within six weeks.

Anyone who reads the police reports must be struck by the number of apparently purposeless crimes that are committed. It is not to be wondered at when we realise how large the proportion is of the "borderland" or semi-insane intellects. Recently a case was reported of a woman who was convicted for the fortieth time. It was added that she was known to be of weak intellect.

Mr. Holmes states that many, the notorious Jane Cakebread among them, who are treated as habitual drunkards are really not dipsomaniacs but are not quite sane. He says: "These people are not what they are because they drink but the reverse: they drink because they are what they are. In a word, drunkenness is not the cause but the result of their condition. Doctors will not, of course, certify them to be insane; until, therefore, the State makes some provision for the half-mad their case is hopeless and frequent tragedies will continue."

As to the immediate suffering and degradation that are due to this disease there can be no doubt. The most horrible house which I ever entered was one to which I went to inquire for a child excused from school attendance. He was brought to me from his bed, his clothes having been pawned as soon as it was known that the attendance officer would not call. It was impossible to unravel the relationships in that family, but there were, I think, three generations of weak-minded persons there; certainly there was an elderly woman of whom it would be difficult to say whether she was most bad or mad, a woman aged 23 years and a boy aged 14 years who were nearly idiots and the little lad on whose account I went. But all this suffering and degradation, terrible as it is, is insignificant compared with the misery we are heaping up for future generations. It has been urged as a reason against taking steps to counteract the evil that if we would let weak-minded persons alone they would die out. Unfortunately that is not so. They die young, it is true. The average life of an idiot is only 20 years. The feeble-minded seem to be generally short-lived in proportion to the degree of their mental weakness. It is rarely, indeed, that children who are weak in mind are strong in body. There seems to be a connexion between congenital deaf-mutes and these children. They are peculiarly susceptible to disease, particularly to consumption, and succumb more readily than normal persons to epidemics. But a great number of them live to have families and their offspring are often more feeble in every way than themselves. This would point to the conclusion that they would in course of time die out, but unfortunately they are not left to themselves: the strong and bad mix with the weak and mad, and so the horrible story goes on and there are always enough accidental cases to renew the strain.

It would be easy to multiply cases and instances in support of what I have said but it is unnecessary. After all, everyone who is acquainted with the sin and misery of our social life has knowledge of one aspect or another of the "feeble-minded problem" and could supply evidence of the existence of the evil. What I am concerned to do is to point out the fact, which many people seem to shrink from recognising, that there is no way of curing this disease in the individual and that the only way of putting a stop to it is to prevent its transmission to the future by careful segregation of the sufferers from their early childhood to their death.

It is grievous to consider the pitiful waste of time and goodness, skill, and money which is involved in treating this trouble temporarily, where it is recognised as existing, and in attempting to cure its symptoms, drunkenness, vice, and crime of every description, where it is not recognised. There is a deplorable futility in convicting a feeble-minded woman forty times, a deplorable loss of power involved in forty times putting all the machinery of the law in operation for one poor creature who was not responsible for her own actions and who should have been placed in happy safety before she was of an age to be dangerous to herself or to society.

It is sad to remember, too, how many charitable agencies are wasting their powers because they do not understand that it is impossible to "rescue" the weak-minded unless it is done once for all. People who deal with these children and see them under control behaving in decent and orderly fashion and generally accepting good habits are apt to forget that the control, and that alone, is the cause of the good behaviour, that so soon as this control is removed the patients are likely to succumb to any other influence which may be brought to bear.

So long ago as 1875 a special committee of the Charity Organisation Society summed up its report thus: "After the period of training a few may be discharged as cured and will become merged in the mass of the population. A large number may be employed as they often are now [employments specified 'at home,' 'in asylums,' &c.]. But, *after making all these deductions* a large proportion of the young persons who have passed through the training schools will prove unfit to be restored to society even under these modified conditions, and for these adult custodial asylums must be maintained at which they may be permanently cared for in the most economical manner, with the advantage of constant medical supervision. But such is the sustaining, healing influence of regular employment that even the adult asylums ought, as far as possible, to be managed on the principle of industrial establishments, having gardens, farms, and workshops of various kinds connected with them to one or other of which every patient capable of doing anything should be attached. Such a system properly carried out would diminish the expense of the institutions "

In connexion with this admirable suggestion it must be remembered that the feeble minded person can never become wholly self-supporting As the late Sir Douglas Galton said, he is in the most favourable circumstances worth only three fourths of a man. But in the least favourable circumstances he is worth considerably less than that. Putting aside for the moment the question of his own happiness or misery, it would be far cheaper to provide for him by supplementing his own earnings in an industrial home than to keep him as a criminal or a pauper

The thing can be done and now is the time to set about doing it. It is well known that these children, so long as they are children, are exceedingly persuadable and affectionate, and that they readily attach themselves to places and persons. When they have once become habituated to the life of the streets, when they have become parents they are much more difficult to deal with, are restless and uneasy and anxious for change and for the excitement which they have once tasted. The special classes provided under the *Elementary Education (Dull and Defective Children) Act* give us the first step necessary towards the permanent care which alone can be effectual in such cases. Children who are acknowledged to be fit subjects for special education in the sense determined by this Act should be under careful medical observation for the last few years of their school life with a view to ascertain whether they are really suffering from mental incapacity If they are they should immediately on leaving the day school (and in some cases before the time for their doing so has arrived), without any disastrous interval spent in learning the lesson of the streets, be transferred to a boarding school and thence again to an adult school, in which they might remain, working and playing, all their lives, children to the end, but happy harmless children, instead of dangerous and degraded ones

IMPROVEMENTS IN THE OPERATION FOR THE RADICAL CURE OF INGUINAL HERNIA BY THE USE OF SOME NEW INSTRUMENTS AND GOLD-WIRE SUTURES.

BY PROFESSOR IGINIO TANSINI,
DIRECTOR OF THE SURGICAL CLINIC IN THE ROYAL UNIVERSITY OF PALERMO

IN the operation for the radical cure of hernia the most careful attention to aseptic precautions is absolutely essential. It is an operation of great practical importance and it is now very frequently performed but its success is not rarely endangered by the occurrence of slight suppuration, while if the suppuration is extensive the result is a complete failure. This suppuration is in the majority of cases due to the use of silk or catgut as sutures. Silk is the better material of the two, for it is less readily absorbed and more easy to sterilise than is catgut, but in spite of very careful sterilisation silk is nevertheless found to cause suppuration in a large percentage of cases Suppuration sometimes occurs early, even within the first 10 days after the operation, sometimes, on the other hand, it is postponed and a perfectly successful operation in which primary union has been obtained is followed by suppuration after the lapse of even six or seven months. In the first case there is at least some risk of failure and relapses are possible, and since the patient's stay in bed is prolonged he is apt to imagine that the surgeon is directly responsible for the *mishap*

The circumstance that suppuration may follow healing by primary union, and may in fact not show itself until many months after a most successful result has been obtained, proves that the suture material has either been imperfectly sterilised or that it possesses some property, chemical or physical, which is capable of exciting suppuration or of acting as a focus of infection *conveyed through the blood* Relapses are the consequence of this defect, and relapses sometimes occur even after healing by primary union without any remote suppuration. Many attempts have been made to find a substitute for silk. Silver wire has been suggested and as it is inadvisable for the wire to be left in the wound removeable sutures have been devised, but these latter have for good reasons found little favour with surgeons (1) because they are more difficult of application than are the ordinary sutures; and (2) because if they are removed in 10 or 12 days the support is withdrawn too soon, while if they are left longer in position the duration of the treatment is correspondingly increased. In order that silver wire may have sufficient strength it must be of considerable thickness, and it is then open to the objection that in passing through Poupart's ligament it weakens it materially

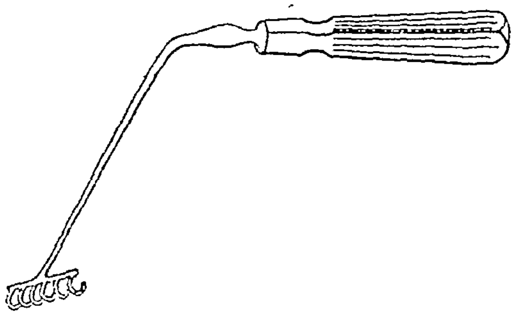
I recommend the use of gold as a material for sutures, for this metal may be drawn into wire which is not only finer than silk but is also stronger and more flexible With such a wire it is as easy to apply sutures as with silk and it cannot do harm as a foreign body The suture is fixed by twisting the ends three times and this requires less time than tying a silk suture. Using this suture and the new instruments to be presently described I have performed the radical operation for inguinal hernia within 10 minutes.

In performing *Bassini's* operation for inguinal hernia, or a modified Bassini, I use thick wire for the deep sutures and much thinner wire for the aponeurosis of the external oblique muscle, for ligaturing the neck of the sac I use the same wire as for the deep sutures and for suturing the sac, if necessary, I use the same wire as for the superficial sutures The ends of the deep sutures are seized with dissecting forceps and turned into the thickness of the internal oblique muscle, the ends of the superficial sutures, which are very thin, are left as they are. After making many experiments with a view to find the most ductile alloy and the smallest possible size of wire I was at last successful thanks to the energy and assistance of the firm of Messrs. E De Amici of Via San Sepolcro, Milan The cost of the wire may at first sight seem to be high but in actual practice the result is an economy The gold which remains in the patient's body weighs only from 12 to 60 centigrammes (from two to 10 grains), the ends of the wires can be preserved, re-melted, and used over again. Moreover, the surgeon may rely on there being no suppuration, especially if along with the gold wire he uses my instruments to be described presently The patient is not kept in bed more than for eight or 10 days, and there is only one dressing in order to remove the sutures inserted in the skin, which sutures may if desired be of silk Silk, however, is not in itself a cheap material, a good deal is required each time that it is used, and much *is apt to be wasted In order to avoid the* necessity of leaving ligatures in the wound I now use torsion for the vessels and I obtain perfect occlusion of them by leaving the artery forceps in position till the end of the operation

Of late years surgeons have given a great deal of attention to the subject of disinfection of the hands, but there are many points in connexion with it which still remain undecided. Gloves are not always worn At an operation the surgeon has always more misgivings about the disinfection of his assistants' hands than about that of his own, for he can avoid coming in contact with obvious sources of infection and can choose the day of operation, but, on the other hand, his usual or occasional assistants, from the nature and variety of their occupations, have more difficulty in keeping their hands clean, so that any device which would obviate the necessity for the assistants to touch the wound would be a great step in advance With the instruments which I have made there is no need for the assistants to touch the wound during an operation for inguinal hernia and the work of the surgeon is also in some degree facilitated In performing Bassini's operation and other similar operations for inguinal hernia I was often not quite satisfied with my assistants, especially with respect to the retraction of the edges of the incision in the aponeurosis of the external oblique muscle and with respect to the depression of the floor of the wound with a view to the easy application of the sutures It was also requisite for me to have two assistants, one of whom had a hand fully occupied with retracting the spermatic cord.

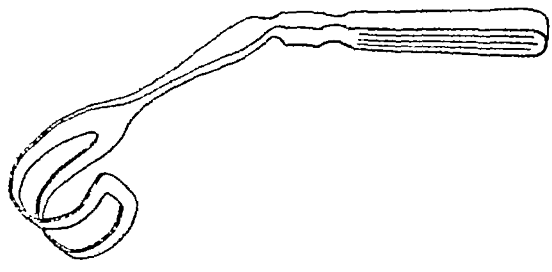
I have now been using my new instruments for more than a year The spermatic cord is intrusted to a hook (Fig 1) which by its own weight and without being held by anyone *keeps* the cord out of the way of the sutures, and the handle of the instrument, on account of its curve, remains close to the surface of the body The edges of the aponeurosis of the external oblique muscle which used to slip from the ordinary hooks or from the fingers of the assistants and were sometimes inadvertently included by the needle are now held wide apart and are well protected by two special hooks (Fig. 2) which act automatically and by their curve do not get in the way. The spatula (Fig. 3) serves also to depress perfectly the floor of the wound and to prevent the point of the needle from sinking into it; it thus facilitates passing the needle through Poupart's ligament. It also has a handle of such a length and shape that the hand of the assistant who holds it is some distance from the field of operation.

FIG. 1.



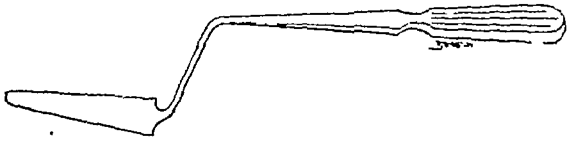
Hook for spermatic cord (actual length nine inches).

FIG. 2.



Retractor (actual length about 10 inches).

FIG. 3.



Spatula (actual length 12 inches).

As evidence of the value of the gold-wire sutures and of the usefulness of the instruments now described the following statistics may be quoted. My operations always included a fair proportion of successes, but before I devised these instrumental aids I had in every 20 cases to deplore one of either early or late suppuration and one relapse in every 70 cases. Now, however, operating in the same place and with the same assistants, out of 150 consecutive operations for the radical cure of hernia, of which not a few were of a serious nature either from their size or from adhesions or from the age of the patient, I have uniformly obtained healing in eight days without any suppuration, early or late, and without a single relapse.

Palermo.

BRISTOL CITY LUNATIC ASYLUM, FISHPONDS.—The forty-first annual report of the Visiting Committee of the Bristol City Lunatic Asylum which has just been issued states that at the end of 1901 the patients numbered 905—viz., 391 males and 514 females, compared with 814 patients (369 males and 445 females) at the close of 1900. The committee adds with regret that it has been necessary to grant Dr. H. A. Benham, the medical superintendent, six months' leave of absence owing to ill health.

A CASE OF PERFORATION OF THE RECTUM INTO THE PERITONEAL CAVITY; LAPAROTOMY; SUTURE; RECOVERY.

BY G. R. TURNER, F.R.C.S. ENG.,
SURGEON TO ST. GEORGE'S HOSPITAL.

A YOUTH, aged 17 years, was admitted into St. George's Hospital on April 17th, 1901, at 4.30 P.M. He said that he was trying to vault over a broomstick and he failed; the broomstick passed up into his rectum, tearing a hole in his trousers and causing much pain and hæmorrhage. On withdrawal the broomstick was covered with fæcal material for about two inches. He was taken to the hospital collapsed and suffering from much pain. He was pale and shivering and vomited three times in the surgery. He was examined by Mr. T. C. English, the house surgeon (to whom I am indebted for these notes), who found a tear of the anus about one inch posteriorly which passed up the posterior wall of the rectum for a short distance. He also thought that he could feel a rent of the anterior wall. The mucous membrane beyond was smooth and fæces were present some three inches from the anus. The examination was difficult and indefinite owing to spasm and pain. The patient was admitted into the hospital and about 10 P.M. he vomited again; there was now much hypogastric pain. The abdomen, which was rigid on palpation, moved well on respiration. I was sent for and at 11.30 P.M., eight and a half hours after the accident, an anæsthetic was given and a rectal examination in the lithotomy position was made. There was an extensive tear of the anterior wall of the rectum which passed through the recto-vesical fold of the peritoneum into the general peritoneal cavity. A sound passed through the rent was found to touch the anterior abdominal wall. There was also a wound of the rectum continuous with the tear of the anus posteriorly.

It was decided to perform laparotomy and, if possible, to suture the rent. A four-inch incision was made above the pubes, fæcal matter and foul fluid being found in the peritoneal cavity. After much difficulty a transverse rent two inches long was found in the peritoneum between the bladder and the rectum, the serous coat being stripped off the posterior wall of the bladder. The examination was aided by an assistant's finger in the rectum. By pulling on the bladder and by the aid of long clips the rent was eventually brought sufficiently near to the surface to admit of suture with catgut. This was effected by long curved needles on handles and a cleft-palate rectangular needle. The peritoneum was carefully cleaned by sponging both before and after suture of the rent and subsequently this neighbourhood was gently irrigated with warm water. The irrigation was not permitted to be more than a local one. A large glass drainage-tube was inserted and some strips of cyanide gauze were passed down to the peritoneal aspect of the rent. Another large tube was introduced into the rectum beyond the tear of the bowel.

The following are the notes of the progress after the operation. On April 18th the patient was doing well. There were no signs of peritonitis. No pain or vomiting was present. The pulse was good. The wound was dressed; much serous fluid came away from the drainage-tube. On each of the two following days the wound was dressed. The patient was doing well. There was slight serous discharge and some of the gauze plugging was removed. On the 22nd the wound was dressed, all the gauze plugging was removed, the glass tube was withdrawn, and a smaller india-rubber tube was inserted. Nothing came away from the rectum. On the 24th he was made to lie on his face to facilitate drainage. On the 26th a little flatus was passed by the abdominal wound. On May 1st the tubes were removed. The bowels had not acted since the operation. He was given half an ounce of castor oil. On the 2nd about one and a half ounces of fæcal material came through the abdominal wound. On the 3rd (16 days after the operation) more fæcal material flowed from the wound and a normal motion was passed by the bowel. On the 4th there was less discharge from the wound. The stitches were removed. On the 5th there was a normal motion by the rectum. On the 7th he passed a

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8849 births and 5015 deaths were registered during the week ending March 22nd. The annual rate of mortality in these towns, which had been 23·3, 20·5, and 19·6 per 1000 in the three preceding weeks, further declined in the week to 17·6 per 1000. In London the death-rate was equal to 18·8 per 1000, while it averaged 17·1 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 7·5 in Handsworth, 9·2 in Ipswich, 9·7 in Hornsey and in Grimsby, 9·8 in Barrow-in-Furness, 10·0 in Aston Manor, and 10·4 in West Hartlepool; the highest rates were 21·1 in Sunderland, 22·1 in Stockport, 22·9 in West Bromwich, 23·0 in Rochdale, 25·1 in Merthyr Tydfil, 27·0 in Devonport, and 29·7 in Burnley. The 5015 deaths in these towns in the week included 553 which were referred to the principal zymotic diseases, against 571, 601, and 617 in the three preceding weeks; of these 553 deaths 149 resulted from measles, 116 from whooping-cough, 93 from diphtheria, 68 from small-pox, 50 from scarlet fever, 46 from diarrhœa, and 31 from "fever" (principally enteric). No death from any of these diseases was registered in the week in Hornsey, Bournemouth, Ipswich, Norwich, Handsworth, Wigan, or Tynemouth; while they caused the highest death-rates in Willesden, West Ham, Walsall, Smethwick, Burnley, Blackburn, York, and South Shields. The greatest proportional mortality from measles occurred in Willesden, Northampton, Great Yarmouth, Grimsby, Warrington, Burnley, Rotherham, and York; from scarlet fever in Reading, Burton-on-Trent, and Burnley; from diphtheria in West Ham, West Bromwich, Salford, and Blackburn; from whooping-cough in Aston Manor, Liverpool, Middlesbrough, and South Shields; from "fever" in Smethwick; and from diarrhœa in Walsall. Of the fatal cases of small-pox registered in the week, 53 belonged to London, five to West Ham, three to East Ham, three to Tottenham, two to Swansea, one to Willesden, and one to Leyton. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 1309, 1508, and 1542 at the end of the three preceding weeks, had further risen to 1567 on Saturday, March 22nd; 449 new cases were admitted during the week, against 369, 554, and 450 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2185, against numbers decreasing from 3137 to 2206 on the 12 preceding Saturdays; 258 new cases were admitted during the week, against 215, 277, and 266 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 733, 589, and 493 in the three preceding weeks, further declined during the week to 388, and were 83 below the corrected average. The deaths in London directly attributed to influenza, which had been 103, 89, and 67 in the three preceding weeks, further declined last week to 39. The causes of 50, or 1 0 per cent., of the deaths in the 76 large towns during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Salford, Leeds, and 45 other smaller towns; the largest proportions of uncertified deaths were registered in Smethwick, Liverpool, Wigan, Preston, and Halifax.

In 76 of the largest English towns 8139 births and 5175 deaths were registered during the week ending March 29th. The annual rate of mortality in these towns, which had been 20 5, 19·6, and 17·6 per 1000 in the three preceding weeks, rose again to 18·2 per 1000 last week. In London the death-rate was 18·4 per 1000, while it averaged 18·1 in the 75 other large towns. The lowest death-rates in these towns were 6·2 in Hornsey, 7 8 in Reading, 9 7 in Grimsby, 10·8 in Walthamstow, 11·3 in Burton-on-Trent, 11 7 in Bury, 12·1 in Leyton, and 12 2 in Handsworth; the highest rates were 21·3 in Manchester, 21·8 in Rhondda, 22·0 in Huddersfield, 22·1 in Stockport, 25 4 in Burnley, 26·0 in Wallsall, 26·1 in St. Helens, and 34·1 in Merthyr Tydfil. The 5175 deaths in these towns included 602 which were referred to the principal zymotic diseases, against 601, 617, and 553 in the three preceding weeks; of these 602 deaths 157 resulted from whooping-cough, 145 from measles, 93 from diphtheria, 68 from small-pox, 52 from scarlet fever, 49 from diarrhœa, and 38 from "fever" (principally enteric). No death from any of these diseases was registered last week in Hornsey, Bournemouth, Ipswich, Great Yarmouth, Devonport, Coventry, Derby, West Hartlepool, or Tynemouth; while the highest zymotic death-rates were recorded in Willesden, Bootle, St. Helens, Burnley, Blackburn, Barrow-in-Furness, Stockton-on-Tees, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in St. Helens, Burnley, Blackburn, Barrow-in-Furness, and Merthyr Tydfil; from scarlet fever in Walsall, Kings Norton, and Middlesbrough; from diphtheria in Birkenhead and Rhondda; from whooping-cough in Leyton, Plymouth, Wallasey, Stockton-on-Tees, and South Shields; and from "fever" in Northampton and Bootle. 68 fatal cases of small-pox were registered last week among persons belonging to the 76 large towns; of these, 61 belonged to London, two to Tottenham, two to West Ham, and one each to Croydon, Leyton, and Liverpool. There were 1526 cases of small-pox under treatment in the Metropolitan Asylums hospitals on Saturday, March 29th, against 1508, 1542, and 1567 at the end of the three preceding weeks; 389 new cases were admitted during the week, against 554, 450, and 449 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had decreased from 3137 to 2185 on the 13 preceding Saturdays, had further declined to 2147 at the end of last week; 250 new cases were admitted during the week, against 277, 266, and 258 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 589, 498, and 388 in the three preceding weeks, further declined last week to 360 and were 60 below the corrected average number. The causes of 63, or 1·2 *per cent.*, of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Manchester, Newcastle, and in 44 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Coventry, Wigan, Warrington, Barrow-in-Furness, Halifax, and Tynemouth.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 25 4 and 23·6 per 1000 in the two preceding weeks, rose again to 23·7 per 1000 during the week ending March 22nd, and exceeded by 6·1 per 1000 the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 12·5 in Perth and 18·2 in Greenock to 25·8 in Aberdeen and 26·3 in Paisley. The 767 deaths in these towns included 28 which were referred to whooping-cough, 25 to diarrhœa, 11 to measles, six to small-pox, five to scarlet fever, four to diphtheria, and four to "fever." In all 83 deaths resulted from these principal zymotic diseases during the week, against 69 and 85 in the two preceding weeks. These 83 deaths were equal to an annual rate of 2 6 per 1000, which was 0·7 per 1000 above the mean rate from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 20 and 23 in the two preceding weeks, further rose again in the week to 28, of which 15 occurred in Glasgow, four in Edinburgh, four in Aberdeen, three in Dundee, and two in Paisley. The deaths from diarrhœa, which had been 13, 17, and 23 in the three preceding weeks, further increased to 25 during the week, and included 12 in Glasgow, five in Dundee, four in Aberdeen, and two in Leith. The fatal cases of measles, which had been 14 in each of the two preceding weeks, declined in the week to 11, of which six were registered in Glasgow and two in Dundee. The deaths from small-pox, which had been 10, two, and seven in the three preceding weeks, decreased again to six and were all recorded in Glasgow. The fatal cases of scarlet fever, which had been seven and eight in the two preceding weeks, declined in the week to five, of which three were registered in Greenock. The deaths from diphtheria, which had been seven and six in the two preceding weeks, further declined to four in the week and included two in Edinburgh and two in Dundee. The four fatal cases of "fever" corresponded with the number in the preceding week and included two in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 230 and 189 in the two preceding weeks, rose again to 217 and were 91 in excess of the number in the corresponding period of last year. The causes of 30, or nearly normal motion. The wound was healing well. A slight but not foul, discharge came from the abdominal wound. On the 20th the wound had firmly healed and the patient was up and about. On the 30th, on examination the whole of the rectum was found to be healed and the rectal wall was quite smooth all round. On June 9th the patient was discharged. The temperature for a week after the operation was 99·2° F. at night, otherwise it was normal throughout.

I have been unable to find any case quite similar to this one. Fæcal extravasation into the peritoneal cavity following perforation of the rectum is a rare condition and I know of no case that has been successfully treated by laparotomy. Some years ago I operated on a case of perforation of the rectum and bladder by a branch of a tree. The patient was a boy who whilst climbing a tree fell and staked himself. I did not see him until more than 12 hours after the accident and although I was able to sew up the bladder rent I found his small intestine was also injured. He survived the operation about 24 hours. I attribute the recovery in the case related above mainly to the gauze packing and drainage and to our successful attempts to limit the contamination of the peritoneum to the parts immediately around the wound of the rectum. The suture of the rectal wound was very difficult. The stitches had to be put in as best one could and it was not at all certain that they were confined to the serous and muscular coats.

Half Moon-street, W.

A SHORT NOTE ON THE USE OF LINEN SEWING-MACHINE THREAD FOR LIGATURES AND SUTURES.

BY ARTHUR E. J. BARKER, F.R.C.S. ENG.,
SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

THE question what ligatures and sutures it is best to employ in any given case is one which must often engage the attention of all surgeons of any large experience. A mere glance at the list of materials employed at different times for the purposes in point must convince anyone that there is still a difference of opinion as to which is best. Most of us have, I suppose, in former times used the old hempen thread and silver wire, then catgut in all its forms, also kangaroo tendon and ox aorta, as well as silk of different kinds, silkworm-gut and horsehair, and, finally, celluloid hemp. Each has been shown to have its advantages but with each there is some drawback. The object of these few lines is to draw attention to a material certainly not new but which probably for its very commonness appears to have been but little used either as a ligature or suture material and which after an experience of nearly two years I find to possess many merits. This is *linen* thread now made for the ubiquitous sewing-machine of the tailor and seamstress. I have used this now in a very large number of cases during the last two years, indeed, almost exclusively and I find it to possess the following good points. In the first place, it can be procured everywhere all over the world wherever there is a depôt for Singer's sewing-machines for which, I believe, it is specially spun. It is relatively very cheap. It can be easily sterilised by boiling in plain water and then stored in methylated spirit. It is enormously strong and ties a most uncompromising knot. It is easy to work with and runs through the eye of any suitable needle easily, having been spun with special care in order to travel evenly through the sewing-machine needle. I have used several sizes and now limit these to three—viz., No. 40, which is as thick as need be desired for the abdominal wall or ligature of the larger arteries; No. 60, which is thinner but still very strong; and No. 90, which is as fine as can be desired, say, for a suture of the intestine. I find it convenient to procure No. 40 as a white thread, No. 60 in red, and No. 90 in black. I have prepared it by simply boiling it for an hour in ordinary water and then keeping it in spirit. A little of the dye comes out of the finer sizes in boiling but does not appear otherwise to alter the thread which can be boiled over and over again without rotting it.

One of the greatest tests of such a thread, to my mind, is an enterectomy or a gastro-enterostomy, and here I have given it a wide trial and have not yet known it to behave in any but the most satisfactory manner. Many of my patients are now going about with it in both stomach and intestine. But where it can be seen in the skin, as, for instance, in the long wound of a breast amputation, its non-irritating nature can be studied *where it has not been tied too tight*. It comes out at the end of 10 days or so just as it went in.

I cannot help thinking that to those who work in out-of-the-way places and who often find it difficult to obtain the usual traditional materials of good quality this *linen* thread will prove a boon. It probably is not absorbed at all but appears to be none the worse for this. Cotton thread is not strong enough in my experience for surgical ligatures and, moreover, rots if much boiled. But this *linen* material is different and the flax fibre of which it is made is long and very smooth.

Harley-street, W.

MENINGO-ENCEPHALOCELE.

BY EDGAR DU CANE, B.A., M.B. R.U.I.

AN infant, aged three and a half days, with a tumour in the occipital region, was brought to me by the midwife for operative treatment. The mother, aged 35 years, had had five healthy children at full term and one still-born, the cause being unknown, and the present child was born after an interval of 10 years. No particular difficulty appeared to have occurred during labour and apart from the tumour the child appeared well-nourished and to have been born at full term. The tumour was found to be two-thirds the size of the child's head, globular in shape, and connected with the occipital region by a large circular peduncle covered with hair. The skin at the posterior portion was much thinner than elsewhere, being practically only membrane. Pulsation occurred when the child cried and besides the presence of fluid, evidenced by fluctuation, there were some solid contents. The connexion with the cranial cavity seemed to be between the centres of ossification of the occiput. I diagnosed the case as one of meningo-encephalocele and having explained to the parents the probability of a fatal termination whether an operation was performed or not I proceeded at their request to remove the tumour.

Having rendered the parts aseptic I aspirated four ounces of fluid and then, dissecting the skin back from the membranes, I separated each layer in the manner of treating a strangulated hernia and finally came upon the posterior portions of both occipital lobes. As these could not be returned into the cranial cavity I carefully excised the protruding portions which on examination proved to be immediately behind the angular gyrus. Bleeding vessels were tied or twisted, membranes were removed, and the edges of the membranes were stitched together; the skin was sutured and a firm pad of antiseptic gauze was applied. The child cried, took the breast, passed urine and defecated naturally, and presented no signs of paralysis and no convulsions. The wound healed rapidly without suppuration and only on the third day was there any rise of temperature, when it reached 100° F., falling on the same night. After 14 days of uninterrupted progress the child had a convulsion and finally died 16½ days after the operation.

The post-mortem examination showed almost complete cicatrisation of the cerebral lesion, but the brain was adherent to the membranes and the latter to the operation wound. There were no pus and but little fluid in the cranial cavity nor was there any great distension of the ventricles. Apart from the cicatrisation extensive congestion was absent.

My reasons for operating were as follows. 1. The disease, if left alone, is usually speedily fatal.[1] 2. Dr G. A. Wright of Manchester[2] says that "attempts have been made to excise the tumours with sufficient success to encourage further trials in selected cases." 3. Dr D. Ferrier[3] states that "though the occipital lobes are included in the visual centres it is nevertheless a remarkable fact that they can be injured, or cut off bodily, almost up to the parieto-occipital fissure on one or both sides simultaneously without the slightest appreciable impairment of vision." He further adds[4] that "Horsley and Schäfer inform him that the results of removal of the occipital lobes in their experiments entirely harmonise with his as to the completely negative effect of this operation on the animal's visual and other faculties." Schatz[5] records a cure in three cases by *constricting* the peduncle with clamps. Dr. Wright[6] excised an occipital meningo-encephalocele in which a piece of the cerebellum of the size of a walnut was removed. The child recovered though it developed hydrocephalus after the operation. Sir Eric Erichsen[7] mentions a case in which a portion of the brain—whether cerebrum or cerebellum is not stated—was sliced off, the patient surviving, but he gives no further particulars and no reference to any records of the case. Mr. T. R. Jessop[8] of Leeds records a successful case of excision but there was no protrusion of cerebral substance or distinct communication with the cranial cavity. Professor T. Annandale[9] in a case where sloughing of a portion of the tumour was taking place ligatured the peduncle and removed the tumour, the child recovering completely in spite of an attack of measles. Dr. Wright in a private communication to me says that "so far as he remembers the other cases he has operated upon have all been meningoceles only."

SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

A CASE OF PERFORATED DUODENAL ULCER; CŒLIOTOMY; RECOVERY.

(Under the care of Mr. R. H. LUCY.)

THE diagnosis of duodenal ulcer is often extremely difficult. It is certainly more common in men than in women; according to Krauss's statistics nearly 10 cases occurred in men for one case in a woman (58 cases to six). In the following instance the sex of the patient and the fact that the abdominal rigidity was specially marked to the right of the middle line pointed to the perforation being situated in the duodenum rather than in the stomach. The differential diagnosis, however, is not of any great importance when perforation has occurred, for laparotomy must be performed in either case Especially noteworthy in the case recorded below is the fact that after recovery from the operation the patient was no longer troubled by the dyspeptic symptoms from which he had suffered for two or three years.

A horse-driver, aged 61 years, was lifting some poles on to a wagon in the afternoon of Jan. 10th, 1898, when he felt a severe sharp pain about one inch above, and to the right of, the umbilicus. He walked home, put up the horses, and about 5 P.M. commenced "to cry and groan" with pain and vomiting set in. For two or three years previously he had suffered from pain at the close of nearly every meal and for his own comfort kept to "slops," but he had never had hæmatemesis or melæna. His wife considered the present attack to be an aggravation of his dyspepsia but eventually called in Mr. C. H. Stevens of Plympton who sent the man into the South Devon and East Cornwall Hospital under the care of Mr. R. H. Lucy about noon on the following day.

On admission the upper abdomen was very rigid and tender (though retracted), particularly to the right of the middle line. *As the signs and symptoms pointed to* duodenal perforation having occurred some 20 hours before Mr. Lucy opened the abdomen in the middle line and found turbid bile-stained fluid. On searching a small punched-out ulcer in the second part of the duodenum was found and was with great difficulty sutured transversely with Lembert sutures of fine silk. The right kidney pouch and the under surface of the liver were cleansed of fluid and lymph but a drain was not employed. The parietes were united with great difficulty owing to the tautness of both recti which persisted even under deep anæsthesia. The patient made a good recovery and was last seen on Jan. 19th of this year, just over four years after the operation. He was then well and hearty, was able to do a hard day's work, had put on flesh, and could "eat anything" without the slightest discomfort, though absolutely edentulous, and the bowels acted naturally every day. Unfortunately the scar had given way and there was a large ventral hernia with wide separation of the recti, but it was perfectly reducible and with the wearing of a stout belt he suffered no inconvenience.

Remarks by Mr. LUCY.—Judging from Mr. B. G. A. Moynihan's paper in THE LANCET of Dec. 14th, 1901, p. 1656, and the cases reported by Dr. Cyril Ogle and Mr. A. Marmaduke Sheild in THE LANCET of March 29th, p. 890, the notes of the above successful operation (for which I am mainly indebted to our late house surgeon, Mr. J. Dill Russell) may be of value. The points of interest are, I think, as follows: (1) the history of indigestion at the close of meals but never any hæmatemesis or melæna; (2) the fact that the patient *walked* home nearly half a mile and put up his horses without help and did not take to his bed for one and a half hours after the perforation had occurred; (3) the actual retraction of the epigastrium some 19 hours after extravasation of duodenal contents and the rigidity of the right rectus when compared with the left muscle; and (4) the difficulty experienced in suturing the parietes with the subsequent giving way of the scar is a result which determines me now when opening the abdomen above the umbilicus to enter between the separated fibres of one or other rectus.

PLYMOUTH BOROUGH ASYLUM.

A CASE OF PERFORATING GASTRIC ULCER; LAPAROTOMY; RECOVERY.

(Under the care of Dr. W. H. BOWES and Mr. R. H. LUCY.)

THE percentage of successes in the operative treatment in perforation of gastric ulcer is steadily increasing with the increasing early recognition of gastric perforation. Unfortunately it is often very difficult to diagnose a gastric ulcer in the absence of hæmatemesis, otherwise perforation might be rendered rarer than it is at present. The following case demonstrates the importance of keeping the stomach empty in the interval between diagnosing gastric perforation and the operation. In all cases of perforating gastric ulcer it is desirable that bacteriological examination should be made of the peritoneal contents, for the issue of the case must depend in no small degree on the form of microbic infection present.

A nurse, aged 25 years, with a history of 18 months' indigestion, was taken with sudden pain and "a feeling of something having burst inside her" at 5.30 P.M. (after a meal of tea and fried potatoes) on Dec. 17th, 1901. At 7 P.M. she went to bed and on her own initiative took a draught containing 20 grains of chloral and 20 grains of potassium bromide. Becoming worse she was seen by the medical officers at 9.30 P.M. who found her collapsed, in excruciating pain, with rigid abdomen and great epigastric tenderness. She had vomited slightly (no blood) twice. A perforating gastric ulcer was diagnosed; a hypodermic injection of morphia was given, turpentine stupes were applied, and she was ordered to keep as still as possible and not to take anything by the mouth. On the morning of the 18th Mr. R. H. Lucy was asked to operate. At 10.30 A.M. the abdomen was opened through the left rectus muscle and on incising the thickened vascular parietal peritoneum gas escaped freely, together with bile-stained mucus. An ulcer three-sixteenths of an inch in diameter was found on drawing down the lymph-coated anterior stomach wall in the line of the parietal incision and half an inch below the margin of the liver. The perforation was closed with eight or nine Lembert sutures of silk, the left kidney pouch was carefully dried out, and the omentum and transverse colon were cleansed and replaced. For 60 hours after the operation nothing was given by the mouth. Nutrient and saline enemata relieved the thirst. Fluid diet was then commenced with two-drachm doses half-hourly of milk-and-water and gradually increased. Light farinaceous (Benger's) food was first given on the 25th and after that date she gradually advanced to ordinary rations. On the 22nd for a few hours there were severe pain and collapse. There was some foul suppuration around the skin sutures for which chinosol fomentations were used. The sutures were removed on the ninth and tenth days. The patient left her bed on Jan. 1st and returned to duty on Jan. 18th. She is now in excellent general health and has *not had indigestion since the operation.*

Remarks by MR. LUCY.—The foregoing case is of interest as showing the value of early accurate diagnosis and the effect on the post-operative progress of withholding strictly everything by the mouth when perforation is once diagnosed. The history of precedent dyspepsia, a tender epigastrium, and occasional vomiting, together with the sudden onset of pain and collapse, the rapid thoracic respiration, tympany over the whole liver area, but marked dulness in the left hypochondriac and lumbar regions, all made up a clinical picture of sudden gastric perforation. Cœliotomy was performed about 17 hours after perforation and the ultimate good result was largely due to the withholding of all oral feeding by Dr. Bowes and Dr. H. B. Wilkinson. The absence of hæmatemesis here (as in all perforating cases that I have so far seen) is noteworthy.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tropical Abscess of the Liver.

THE following concludes our report of the meeting of this society held on May 13th (*vide* THE LANCET, May 17th, p. 1397).

DR. PATRICK MANSON, in discussing MR. RICKMAN J. GODLEE's paper on Tropical Abscess of the Liver (which is published at p. 1452 of our present issue), said that the operation he had suggested—namely, plunging in a trocar and inserting a drainage-tube through it, was only suitable for ordinary use or in tropical countries where experienced surgeons were not so plentiful. It was a simpler operation. He would like to ask why it was that abscesses in the upper part of the liver extended the liver dulness upwards instead of lowering the liver as a whole. He doubted if the escape of a little pus into the peritoneum in these cases was attended by very great danger.

DR. A. CROMBIE remarked that he had been treating cases of hepatic abscess for 30 years. It was the practice in India to use Dieulafoy's aspirator and in small abscesses this was sufficient and the patient recovered. Even in larger abscesses one or two such operations were sufficient. In one case he had aspirated 14 times and the case resulted in recovery. He thought that all suitable cases should be treated in this way, at any rate in the first instance. In all his cases he had never found it necessary to stitch the liver to the wall before opening the abscess. He quite agreed with Dr. Manson that no damage resulted, as a rule, from the leakage of pus into the peritoneum.

MR. JAMES CANTLIE had used Dr. Manson's trocar in 34 cases in all and thought that its convenience was very great; very often the surroundings of such cases were very unfavourable. The danger of hæmorrhage from a hepatic vein was also obviated in this way. The drainage-tube should be an indiarubber one.

DR. W. G. ROCKWOOD had operated on upwards of 100 cases in 25 years. He had employed the method suggested by Dr. Manson many times. In his earlier cases he aspirated. He sometimes found it necessary to aspirate a second or third time. Lately it had been his practice to excise a portion of the rib.

MR. GODLEE, in reply, said he was bound to confess that he had not seen any very serious consequences from the escape of the pus into the peritoneum, but on one occasion the patient had some pain which might have been produced in this way when the liver was not stitched to the abdominal wall. As regards aspiration this suggestion had been made in cases of empyema, but sooner or later they always *needed a more complete operation.*

PATHOLOGICAL SOCIETY OF LONDON.

Infective Lesions of the Tongue, Stomach, and Intestines in Addison's Anæmia (Pernicious Anæmia).—Joint Lesions in Hæmophilia.—Congenital Atresia of the Small Intestine.—Fibrinous Cast of the Gall-bladder.—Hæmorrhage into the Adrenal Bodies.—Disseminated Carcinoma simulating Tubercle.—Annual General Meeting.

A MEETING of this society was held on May 20th, MR. W. WATSON CHEYNE, C.B., the President, being in the chair.

DR. WILLIAM HUNTER made a communication on the Infective Lesions of the Tongue, Stomach, and Intestines found in Addison's Anæmia (Pernicious Anæmia). This paper (which was illustrated by a lantern demonstration) was an extension of the researches previously recorded.[1] The present results were based upon 25 cases of pernicious anæmia which had come under his (Dr. Hunter's) observation during the past two years. In pernicious anæmia (the disease described by Addison in 1855) there was a hæmolysis which was not found in the numerous other varieties of anæmia described by various authors and which were attributed by them to a great variety of causes, such as poverty, ulcer of the stomach, ankylostomiasis, hæmorrhages, &c. Sepsis alone was incapable of giving rise to true pernicious anæmia, for in septic anæmia there was no evidence of hæmolysis in the liver. The evidence on which Dr. Hunter's conclusions had been based was of three kinds—(1) the prevalence of oral sepsis (gingivitis, decayed teeth, &c.) in connexion with the disease; (2) the existence in these cases of a subacute infective gastritis as one result of long-continued oral sepsis and mucoid vomit containing streptococcus longus; and (3) the occasional prevalence of infective lesions in the mucosa of the alimentary canal, probably having a similar origin. The present communication was based on the bacteriological and histological examination of the 25 cases recently observed. Necropsies had been performed on seven of these, from which 1145 sections had been made and some 250 cultures had been made. A peculiar form of glossitis had been found in every one of the 25 cases. Special observations had been made on the tongue, clinical and anatomical. There was great thinning of the mucosa which in places was quite wanting, so that the *lymphatics of the tongue* were practically in direct continuity with the buccal cavity. It was this thinning of the mucosa which produced the glossy condition of the surface of the tongue which Dr. Hunter regarded as quite peculiar to the disease. He had obtained pure cultures of streptococcus longus from the lymphatics of the tongue. These had been injected into mice and killed them in six or seven days. The only other disease in which anything resembling this condition of tongue was psilosis, but Dr. Hunter was not sufficiently familiar with the latter disease to speak definitely. In the *stomach* he had found an inflammatory condition of the mucosa extending down almost to the submucosa. The epithelium was thrown off in large quantity as mucoid vomit and in the final stage complete atrophy of the gastric mucosa occurred. Marked lesions in the intestines had also been found. The mucoid vomit which was vomited in the morning contained pure cultures of *streptococcus longus.* The conclusion which Dr. Hunter had arrived at was that there was a double infective process: (1) a specific infection, of which the chief evidence was a glossitis; and (2) a septic infection of the mouth, stomach, and intestine, of which the chief evidences during life were varying degrees of "oral sepsis" and "septic gastritis," the latter recognisable during life by the vomit and various symptoms of oral gastric and intestinal disturbance, and after death the conditions of gastritis, gastric atrophy, intestinal atrophy, erosions, or ulcers now and again found in the disease.

MR. A. LUCAS (Birmingham) exhibited an Unusual Variety of Joint Lesion in a case of Hæmophilia. The patient was a boy, aged 10½ years, who had been an out-patient under the care of Mr. Lucas for about four years, suffering from hæmophilia and who was accidentally drowned whilst at play. He had had repeated hæmorrhages into the knee-joints, more frequently into the right joint. There was much enlargement of this joint, the synovial membrane was thickened, and the ends of the bones also appeared to be enlarged. There were no adhesions; the synovial membrane was thickened and the fringes were hypertrophied and stained from the repeated hæmorrhages. The cartilages were slightly lipped at their free margins as in osteo-arthritis. The articular surfaces showed many irregular pits where in places the cartilage had entirely disappeared. This condition was most marked where there had been pressure of the cartilaginous surfaces, but there appeared to be no rubbing away of the cartilage.

---

[1] THE LANCET, Jan. 27th (p. 221) and Feb. 3rd (p. 296) and 10th (p. 371), 1900.

Mr. LUCAS also communicated a case of Congenital Atresia of the Small Intestine which had occurred in a male child, aged three days, who was admitted into the Birmingham General Hospital with symptoms of intestinal obstruction including fæcal vomiting.

Dr. H. D. ROLLESTON showed a Fibrinous Cast of the Gall-bladder removed during Cholecystotomy by Mr. Herbert Allingham from a woman, aged 52 years. The gall-bladder was much enlarged and adherent to adjacent parts. It contained a large single gall-stone of the size of a walnut which was enveloped in a fibrinous cast. The cast was easily separable from the walls of the gall-bladder and resembled a dysmenorrhœic cast of the uterus. Histologically the membrane was composed of a fibrinous network inclosing crystals and bile pigment. The case was an example of fibrinous or membranous cholecystitis. This lesion was not analogous to that of mucous colitis where the intestinal casts were composed of coagulated mucus.

Dr. CLIVE RIVIERE exhibited four specimens of Hæmorrhage into the Suprarenal Capsules from cases occurring at the Shadwell Children's Hospital. The cases were characterised clinically by vomiting, diarrhœa, a purpuric eruption, and a high temperature, and ran their course to a fatal termination in from 12 to 48 hours. The condition of the suprarenals was different from that of circumscribed hæmorrhage since there was a diffuse infiltration with blood. Besides the suprarenal lesion in these cases there was swelling of Peyer's patches and mesenteric glands. It was suggested that the cause might be food toxins or a toxæmia due to a bacterial infection of the intestine. The former seemed unlikely from the insidious course of the early symptoms. The latter explained the condition most satisfactorily.

Dr. F. J. SMITH exhibited specimens from a case of Disseminated Carcinoma simulating Tubercle.

The annual general meeting was held at the conclusion of the ordinary meeting. The report of the council was read and adopted. The re-arrangement of the society's meetings had lead to a satisfactory increase in the attendance of members. A general index of the Transactions had been issued. Owing to the expense of printing the Transactions it would be desirable to adopt some means of retrenchment in the society's expenditure.—Votes of thanks were proposed and carried to the retiring President, Vice-Presidents, members of council, and secretaries.

The following officers and council were duly elected for the year 1902-3:—President: the Right Hon. the Lord Lister. Vice-Presidents: Mr. R. J. Godlee, Dr. W. D. Halliburton, Dr. E Klein, and Dr. F. W. Pavy. Treasurer: Dr. Sidney Coupland. General secretary: Mr. S. G. Shattock. Sectional secretaries: Dr. H. Morley Fletcher, Mr. A. G. R. Foulerton, Dr. T. Grigor Brodie, and Dr. A. E. Garrod. Council: Dr. R. Crawfurd, Dr. J. Fawcett, Dr. L. Freyberger, Dr. N. Dalton, Dr. G. F. Still, Dr. T. W. P. Lawrence, Dr. S. H. Habershon, Dr. F. W. Andrewes, Dr. W. Bulloch, Dr. John McFadyean, Dr. Allan Macfadyen, Mr. H. G. Plimmer, Dr. R. T. Hewlett, Dr. W. S. Lazarus-Barlow, Dr. J. R. Bradford, Dr. E. H. Starling, Mr. C. A. Ballance, Dr. F. G. Hopkins, Dr. V. Harley, and Dr. S. G. Hédin.

OBSTETRICAL SOCIETY OF LONDON.

Fibroid Tumour of the Ovary.—Lymphangitis Mammæ.—Exhibition of Specimens.

A MEETING of this society was held on May 7th, Dr PETER HORROCKS, the President, being in the chair.

Dr. JOHN S. FAIRBAIRN read a paper on Five Specimens of Fibroid Tumour of the Ovary, with Observations on their Pathological Anatomy. Attention was first directed to the descriptions of these growths as given in the text-books and monographs on the subject. The general statement was that these tumours were formed by hyperplasia of the whole stroma, so that the organ was converted into a hard tumour retaining more or less the original shape of the ovary. Five specimens, varying in size from a small growth of the size of a hen's egg up to a large tumour of over four pounds in weight, were described in detail. In all of them the new growth had arisen within the ovary and affected only a portion of the stroma, leaving a considerable part of the organ as a separate and easily recognisable structure. The microscopic appearances were also noted and a short clinical history of the cases from which they were obtained was added. After looking through a large number of recorded cases of fibroma and fibro-myoma of the ovary, some 15 or 16 were selected as similar to those described in the paper and a short abstract of them was given. When such specimens had been shown at societies they had given rise to some discussion from the unusual persistence of a portion of the ovary. The number of instances quoted, together with the five specimens under review, was sufficient to show that the descriptions usually given were misleading. While the difficulty of detecting unstriped muscle cells among fibrous tissue cells was acknowledged, the evidence of a comparative examination of sections from these tumours appeared to be in favour of their being considered fibromata. The sections provided a very good opportunity of contrasting the minute structure of the growth with the ovarian stroma from which they had originated; the results of such a study were adduced in favour of considering these firm hard growths of the ovary as simple fibromata and not as fibro-sarcomata. The question of these tumours arising from a chronic oöphoritis was discussed very briefly and the importance of the tunica albuginea in forming a strong covering to ovarian growths was pointed out. In conclusion, the fibromata of the ovary were divided into three classes for purposes of description. 1. The ovary was entirely replaced by the new formation. This occurred in small as well as large growths and therefore did not depend on the size to which the growth had attained. 2. A local growth of the stroma leaving part of the ovary unaffected, except by compression. The growth tended to remain within the capsule of the ovary. 3. Pedunculated fibromata like subperitoneal fibroids of the uterus. These might either have originated in the stroma and later been extruded or they might be growths of the tunica albuginea.—Mr. ALBAN H. G. DORAN maintained that the three specimens which he exhibited that evening in relation to Dr. Fairbairn's important paper implied that fibroma and myoma of the ovary were distinct diseases. The section of the large fibroma showed perfect wavy white fibre, as did the section of the little solitary fibroma not half an inch in diameter. The myoma, unlike the two fibromas, was closely related to the ovarian ligament, which included muscular tissue derived from the uterus. On section it showed plain muscle cells, precisely as seen in a section of a myoma of the uterus. Œdematous fibroids were once taken for sarcomas of the ovary; subtracting these suspected malignant growths from the malignant solid tumours of the ovary they would probably find that carcinoma of the ovary was much more common than sarcoma, as Martin had demonstrated, whilst fibroma, innocent even when looking malignant, was by no means rare. There were plenty exhibited that night. Mr. Doran noted how the tube and mesosalpinx often underwent little or no hypertrophy in fibroma, so that when the tumour was large it was rather difficult to get at the pedicle.—Mr. J. BLAND-SUTTON congratulated Dr. Fairbairn on establishing the fact that the encapsulation of the tumour could be relied upon as a generic and distinguishing feature. When the fibroid was of moderate size, as in the smallest specimen of his series, the disproportion between the ovary and the tumour was not so marked; but when the mass had a circumference of 10 or even 30 centimetres, or more, then the small bud-like remnant of the ovary at the uterine end of the tumour appeared to be very incongruous. The leading features of these tumours could be summarised thus: encapsulation, ovoid shape, intense hardness, and the whorled disposition of the tissue as displayed on the cut surface. These were a group of signs presented by no other tumour of the ovary and their clinical value was equal to their simplicity. There was an important feature by which ovarian fibroids were distinguished from similar tumours in the uterus. It was well-established that uterine fibroids did not arise after the menopause, whereas ovarian fibroids occurred in the aged, and on two occasions Mr. Bland-Sutton had successfully removed them at the ages of 64 and 66 years and the clinical histories indicated that the tumours had only been noticed two years before removal. The extreme hardness of these tumours was a valuable clinical sign and in one of the cases in Dr. Fairbairn's series Mr. Bland-Sutton was able accurately to diagnose the character of the tumour from this sign alone. The paper was a valuable one, even if only regarded from the point of view that its author had rescued a genus of tumours from a group notorious for containing members with extremely bad characters.—Dr. GRIFFITH fully agreed with the conclusion arrived at by Dr. Fairbairn in his interesting paper. He had endeavoured to show in the paper referred to by Dr. Fairbairn that all tumours of the ovary, whether cystic or solid, were in the main structure of their solid parts connective tissue derived from, and having the essential character of, the spindle-celled stroma of the normal organ. Corpora fibrosa were physiologically the ultimate stages of the corpora lutea and where they were enlarged their structure appeared to remain of the special character of the normal bodies and not spindle-celled.—Dr. H. BRIGGS said that amongst his original cases and amongst recent ones he had figured and noted circumscribed growths to which Dr. Fairbairn had paid conspicuous attention. The early writers were correct in alluding to both diffuse and circumscribed growths.' Dr. Briggs suggested that Dr. Fairbairn had shown a want of courage in selecting fibroids, and not fibromata, as the title of the paper founded on the five cases which he had described. Mr. Alban Doran's specimen exhibited that night, if not actually a myoma, was the nearest approach in its microscopical characters to a myoma of any he had ever seen. Dr. Briggs thought that that would be a general opinion which meanwhile, in the face of so much evidence to the contrary, might be held in reserve. The main danger had been, as Mr. Bland-Sutton said, in ascribing malignant properties to cellular structures without adequate clinical proof. In Dr. Briggs's experience this impeachment was not limited to gynæcologists. The proof of the innocence of cellular growths described as fibromata of the ovary had been substantiated by Mr. Alban Doran and himself in the published paper referred to by Dr. Fairbairn. Dr. Briggs cited the case in which he operated almost immediately after he had published his paper. In a girl, aged 17 years, there was a large, brain like solid growth of the ovary. The girl was still alive and was an active hospital nurse. The tumour was proved to be a highly cellular growth, a myxoma. The rarity, as alleged, of fibromata of the ovary was not justified by facts which had now accumulated. Dr. Briggs added that all his patients from whom he had removed these tumours still lived.—Dr. HERBERT R. SPENCER was surprised at the number of writers cited by the author who regarded ovarian fibroids as diffuse growths involving the whole of the ovarian tissue. His own experience was opposed to such a view, for out of five cases under his own care in four the growth was very definitely limited to a portion of the ovary, and in the fifth (a large tumour) he thought possibly the tumour was so limited, but without spoiling the museum specimen by a series of thin sections it was impossible to settle this point. Ovarian fibroids were certainly benign growths and had much in common with uterine fibroids. The latter did not involve the whole tissue of the uterus but sometimes displaced and compassed it to a remarkable extent. It seemed to him most unlikely that such a benign fibroid growth would invade and destroy the whole of the tissue of the ovary and, as a matter of fact, in the five cases alluded to and in several others he had seen it did not do so. A most interesting point in connexion with these growths not alluded to by any speaker was their origin. Two of his cases suggested, and a third, he thought, clearly demonstrated, the origin of an ovarian fibroid in the tunica fibrosa of a Graafian follicle. This mode of origin had been mentioned by Rokitansky, though he did not know upon what evidence. Patenko's corpora fibrosa were, as Mr. Alban Doran had pointed out, merely degenerated corpora lutea and were entirely different in structure from the fibroids.—The PRESIDENT pointed out that these tumours and also sarcomatous and malignant tumours generally differed from fibroids in that the cut surfaces remained flat, like a cut raw potato, whereas fibroids always became slightly convex on the cut surfaces immediately on being incised, and this convexity gradually increased owing to the shrinking of the elastic and muscular fibres. He considered that it was of great importance to be able to say that a given tumour was a fibroma and innocent, or a sarcoma and malignant, and he hoped the work of Dr. Fairbairn would assist in this direction. He mentioned a case which he had shown himself where equally competent observers had expressed diametrically opposite opinions regarding the microscopic sections. So far as he had gathered the chief distinction seemed to be that in fibromata the blood-vessels were much more clearly defined, but he wished to know if this could be relied upon in deciding.—Dr. FAIRBAIRN briefly replied.

Dr. RALPH H. VINCENT made a communication on Lymphangitis Mammæ, an affection of the breast arising about the tenth day of the puerperium, with well-marked clinical features. He brought forward the notes and temperature charts of six cases illustrating this condition. These cases showed the following clinical signs. There was a wedge-shaped area of inflammation, the apex being at the nipple, the base being at some part of the junction of the breast with the chest-wall. This wedge-shaped area was red, slightly œdematous, hot to the touch, tender, and indurated, the induration being distinctly outlined and definitely corresponding with the redness. The inflamed area was raised above the general breast-surface, but the inflammation was confined to the superficial structures and did not involve the mammary gland. During the development of this condition the temperature rapidly rose, the patient complained of pain in the breast and of headache, whilst constipation was frequently present. The treatment required was simple; the infant was taken from the breast, hot fomentations were applied to the inflamed part, and the patient was freely purged. Within about 48 hours the affection disappeared. He attributed the condition to an infection conveyed to the nipple from the lochia serosa.—Dr. AMAND J. M. ROUTH asked if Dr. Vincent was sure that some of his cases were not small mammary abscesses which had opened suddenly into one of the larger milk-ducts, thus accounting for the sudden cessation of all the symptoms.

Specimens of Fibroma and Myoma of the Ovary were shown by Mr. ALBAN DORAN, Mr. STANLEY BOYD, and Mrs. STANLEY BOYD, M.D.

Dr. W. F. VICTOR BONNEY showed a specimen of very early Twin Pregnancy with Fœtuses of different dates, also a specimen of Early Pregnancy.

Dr. TATE, having shown a Sarcoma of the Uterus complicated by Glycosuria and removed by Vagino-abdominal Hysterectomy, the case was discussed by the PRESIDENT, Dr. M. HANDFIELD-JONES, and Dr. MALINS.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

PATHOLOGICAL SECTION.

Continued Fever due to Gärtner's Bacillus.—Exhibition of Specimen.

A MEETING of this section was held on May 2nd, Professor E. J. MCWEENEY, the President, being in the chair.

Dr. JAMES CRAIG and Professor A. H. WHITE communicated a paper on a case of Continued Fever due to the Bacillus Enteritidis of Gärtner. Dr. Craig said that the patient was an unmarried man, aged 22 years, of temperate and regular habits. About Sept. 18th, 1901, he complained of not feeling well; on the 24th he had shiverings, felt worse, and during the next few days vomited several times; he had slight diarrhœa but felt no pain. On the 30th he visited the Meath Hospital, Dublin, where he came under Dr. Craig's notice. His temperature was 103° F., his pulse-rate was 100, and his respirations were 24; his tongue was furred with a creamy matter, though clean at the tip and along the margins, and when protruded it was seen to be ataxic. He was covered on the front and back of the trunk with rose spots and was suffering from diarrhœa, the stools being thin and yellowish. Typhoid fever was diagnosed and the man was admitted to hospital. The following day the temperature was 104°, his cerebration was slow, he was disinclined to talk, lay on his back, had an eruption of herpes labialis, and in the evening his temperature reached 104·6°. The rash became darker. Sir John Moore saw him in consultation and recommended his removal from the ward, as he looked on the case as one of typhus fever. Professor White examined the blood-serum and found that Widal's reaction took place with a 1 in 25 dilution. During the following days his condition became worse and the diarrhœa more frequent but without either pain or tympany; his spleen was distinctly enlarged. He now refused nourishment and became wildly delirious, having to be held down; he passed his fæces and urine under him unconsciously. He was given black coffee and hypodermic injections of strychnine but no alcohol. He died on the eleventh day after admission to hospital. The necropsy revealed an enlarged spleen and a condition of inflammation of the mucous membrane throughout the length of the small intestine but no enlargement or ulceration of Peyer's patches. Professor White said that the small intestine did not present the ordinary lesions of typhoid fever; the whole mucous membrane was inflamed. The spleen was enlarged and from it he obtained a pure culture of an organism which, though at first sight it appeared to be the typhoid bacillus, he now considered to belong to the bacillus enteritidis group. The organism was a motile bacillus which decolourised by Gram's process and did not liquefy gelatin or coagulate milk; it caused fermentation of glucose but not of glycerine. Professor White exhibited about 20 different cultures of this organism on various media and similar cultures of the typhoid bacillus, bacillus coli, and two known varieties of the bacillus enteritidis given him by Professor O'Sullivan. He had not immunised an animal against this organism but hoped to do so in order to determine, if possible, to which of the varieties of the bacillus enteritidis group this organism belonged. The blood serum from some typhoid patients gave a clumping reaction with this organism at low dilutions only, while the serum of this patient gave a reaction with typhoid bacilli at a dilution of 1 in 25 but not at 1 in 50. Professor White then recounted a number of outbreaks of serious illness following on the eating of meat containing these organisms, in many of which death resulted, and he gave an abstract of Durham's work on the subject. He considered the Gärtner group of micro-organisms to be distinct organisms, not aberrant forms. He looked on the present case as one not of typhoid fever but of fever due to a bacillus having all the morphological, cultural, and pathogenic characters of the bacillus enteritidis.—The PRESIDENT said that he inclined to the idea that the Gärtner organism occupied an intermediate position between the typhoid bacillus and the bacillus coli. The case in its clinical aspects had a striking resemblance to a series of six or eight cases brought forward by Dr. Chiari at the International Medical Congress held in Moscow. In these there were no typhoid lesions but splenic puncture yielded micro-organisms which produced typhoid infection. He looked on the case as one of typhoid septicæmia due to an aberrant bacillus.

Professor C. Y. PEARSON exhibited a Sarcomatous Osteo-Chondroma of the Femur removed by Disarticulation at the Hip on August 22nd, 1901. The patient was a man, aged 57 years. The tumour was of almost stony hardness and measured 31 inches in circumference at its widest part. It was a periosteal osteo-chondroma. The patient made a good recovery but returned in April, 1902, ailing with severe abdominal pain and was found to have a tumour with communicated impulse in the epigastrium.

EDINBURGH OBSTETRICAL SOCIETY.—A meeting of this society was held on May 14th, Dr. James Ritchie, the President, being in the chair.—Professor A. R. Simpson showed (1) an Anencephalous Fœtus with Spina Bifida and Exomphalos; the condition was associated with hydramnios; (2) Dermoid Tumour of the Ovary; (3) Solid Fibroma of the Ovary; (4) Tumour of the Ovary containing Mother and Daughter Hydatids; and (5) Bossi's Dilator for the Cervix, which had four blades and was worked by a screw handle, an indicator showing the amount of dilatation produced; when used for the pregnant uterus rounded guards were slipped over the narrow blades and full dilatation of the cervix could be effected in half an hour without any tearing of the tissues.—Dr. D. Berry Hart showed a Uterus removed for Cancer of the Cervix, a Malignant Tumour of the Ovary, and a Hydrosalpinx.—Dr. F. W. N. Haultain showed (1) an Ovarian Cyst with Double Pyosalpinx which had Ruptured into the Intestine; (2) Probable Ovarian Pregnancy; (3) Uterus removed for Adeno-sarcoma; and (4) Double Monster with fused bodies, two heads, four legs, and three arms, one of which had two hands.—Dr. W. Fordyce showed a Solid Fibroid Tumour of the Ovary.—Dr. Hart, with the aid of diagrams, described the Development of the Amnion and Cord. The current view as to the origin of the amnion and cord, as in the chick, was discussed and the difficulties in accepting it were pointed out. The amnion did not cover the human cord and practically there was no allantois to fix the embryo to the chorion after it had been separated off by the hypothetical folds. From a consideration of Peter's ovum and a similar one in Dr. Hart's possession he concluded that (1) the amnion was formed by the central breaking down of an ectodermic plug as in the guinea-pig (so-called inversion of the membranes); and (2) it was formed early in the development of the embryo and prior to the formation of the cœlom from which the pleuro-peritoneal cavity is evolved.—Professor Simpson and Dr. J. W. Ballantyne made remarks on the subject.—The President read notes on a case of Acute Pyelitis in Infancy.—Dr. John Thomson read a paper on the Symptoms and Treatment of Acute Pyelitis in Infancy. He gave his experience of eight cases observed since Dr. Emmet Holt of New York wrote his paper in 1894. The condition could not therefore be rare. Undiagnosed it was an alarming illness but under proper treatment it was a very curable one. Dr. Thomson's patients were all girls and their ages varied from seven and a half to 20 months, but the disease occurred not uncommonly in older children also. In almost all the published cases the patients had been girls. In one of the eight cases the parents were rheumatic and in another there was a family history of gout. In six cases the previous health had been excellent and in two cases chronic dyspepsia and rickets were present. They had all been artificially fed. Two cases had shown symptoms of infantile scurvy, one severe, the other slight, and influenza had preceded the pyelitis in two cases. In all but one case there had been troublesome constipation; in some there had been occasional attacks of diarrhœa. In five cases at least there was a history either of soreness about the anus or pain during the act of defecation, or blood had been seen in the motions. The symptoms were ushered in generally with a rapid rise of temperature, so that pneumonia or influenza had often been suspected. In no case did convulsions occur, but in four of them there were one or more severe rigors or chills. This occurrence of rigors in an infant was very helpful in the diagnosis of the condition. Even in malaria well-marked signs were said to be rare under two years, though they did sometimes occur. Their place was generally taken by a convulsion. Apart from malaria Dr. Thomson could not find any account of a rigor in a child under two years of age without the presence of pus in the urine. Suppurative or other surgical conditions did not seem to be attended with rigors in young children. The temperature was frequently above 104° F. and its type was more or less remittent, so that the chart often looked like that of enteric fever. The effect of treatment on the temperature was very striking. Another very marked characteristic of the disease was the extreme restlessness and distress which the children displayed, though this was not a constant condition. The appetite was often well maintained and consequently the emaciation might not be rapid. There might be screaming fits as in colic. There might be only uneasiness or slight pain on micturition, but just as frequently there were no symptoms occurring with micturition. There was excoriation or fissure of the anus in five of the eight cases, and in two there was some soreness of the vulva. Tenderness on palpation of the kidney was distinctly evident in two cases. The urine was always acid, generally extremely so; in one case there was a peculiar fœtid odour. Albumin was always present in small amount, but in no case more than could be accounted for by the pus cells present; no tube casts could be found. Pus was always present in considerable amount; sometimes the urine was turbid with it. A few epithelial cells of different shapes were usually to be seen. Blood was only detected in one case where there had been scorbutic hæmaturia not long before. Bacteria were always visible in large numbers in the freshly-passed urine and cultures of the urine gave pure growths of the bacillus coli communis. No crystals were found during the illness but large quantities of uric acid and oxalates had been passed on former occasions. The cause of the disease was the bacillus coli communis and it might reach the pelvis of the kidney by the blood or lymph-stream or up the urethra. The great preponderance of females affected would suggest the last as the usual source. Together with the presence of the bacillus there must be a lowering of the vitality of the tissues. The diagnosis depended on the presence of pus and bacilli in acid urine, the occurrence of rigors (almost conclusive), and any local tenderness, together with considerable fever. The prognosis was favourable; under proper treatment the cases improved rapidly as regards the temperature and symptoms, but it was usually several weeks before the pus disappeard from the urine. The main and the only essential treatment consisted in rendering the urine neutral by the administration of alkaline remedies as speedily as possible. The results were most striking. Dr. Thomson used citrate of potash and it required to be given freely before the urine lost its acidity. 24 grains in the 24 hours might suffice in less severe cases but generally from 36 to 48 grains were necessary. This quantity of alkali was very beneficial but it usually caused depression. The temperature became subnormal and the child became flabby and nauseated. No harm arose, and relapse might occur when the potash was prematurely diminished or discontinued. Antiseptics given alone were not very efficacious but in combination with alkali were helpful. Salol acted well; urotropin seemed less active; creasote was found to be very useful by Baginsky. Holt tried very large doses of quinine with very little effect.—Dr. Ballantyne, Dr. J. Haig Ferguson, Dr. G. Keppie Paterson, Dr. Fordyce, and Dr. H. M. Church discussed the paper and the President and Dr. Thomson replied.

ULSTER MEDICAL SOCIETY.—A meeting of this society was held on May 8th, Professor W. Whitla, the President, being in the chair.—Mr. A. B. Mitchell showed a radiogram of a very Oblique Fracture of the Femur and the patient; also three patients operated on for Abscess due to Spinal Caries.—Dr. T. Houston showed a case of Pernicious Anæmia.—Dr. James Lynass showed a case of Double Talipes Equino-varus treated by excision of the astragalus and a case of extensive Epithelioma of the Lower Lip treated by excision and plastic operation.—In the discussion which followed Mr. A. Fullerton, Mr. R. Campbell, Dr. W. Calwell, Professor J. W. Byers, and Dr. A. Dempsey took part.—Dr. John Campbell exhibited a Myoma of the Uterus and an Ovarian Tumour removed by Abdominal Section.—Dr. J. K. Greenfield read a paper on Some Forms of Peritonitis and their Treatment, the cases being of various kinds, with an interesting account of the treatment employed.—Dr. John Campbell read a paper on the Treatment of Dysmenorrhœa. He approached the subject from the purely clinical standpoint and divided the cases into two main groups—viz., (1) those without pelvic lesions and (2) those with pelvic lesions. The former group included the anæmic and neurotic subjects who required general hygienic treatment and purgatives, tonics, or sedatives according to circumstances. Neurotic subjects were sometimes benefited by the constant electric current with the negative pole in the uterus and the positive on the abdomen, a current of from 20 to 40 milliamperes being used. The second group having pelvic lesions might all be treated by dilatation and curetting of the uterus, followed by the insertion of a gauze uterine drain. This gave good results in some cases and failed utterly in others. The important thing was to select the cases so as to avoid bringing the method into contempt by applying it in unsuitable cases or strongly advising it in doubtful ones. Accordingly cases of dysmenorrhœa with pelvic lesions might be subdivided into three classes—viz.: 1. Those with slightly enlarged or anteflexed or inflamed uteri and normal appendages which were improved by curetting and gauze drainage, which was essentially the treatment for them. 2. Those in which the uterus was approximately normal and the appendages diseased. Here curetting gave results in the main proportionate to the amount of involvement of the uterus. Unfortunately, the appendage mischief so overshadowed the uterine trouble that removal of the latter was hardly appreciated by the patient. The idea so much advocated by American writers that curetting benefited tubal disease was wrong. It benefited the uterus alone and results depended on the relative intensity of the disease in the uterus and tubes. 3. Those in which the uterus was displaced and more or less adherent, the appendages being also affected in varying degrees. Here curetting gave little hope of substantial permanent improvement and should only be done as an experiment when all else had failed. Removal of diseased appendages for dysmenorrhœa was not to be done unless other reasons than pain demanded their removal. Women with painful ovaries were liable to have painful stumps after operation. The breaking down of adhesions followed by ventro-fixation or vagino-fixation was very uncertain in its results. These operations should only be done as a last resource and the patient should not be led to expect too much from them, as they often failed to give her satisfaction. The treatment of bad cases of dysmenorrhœa remained unsatisfactory in spite of our advances.—Dr. C. Kevin spoke of the value of Dr. Campbell's paper to general practitioners.—Professor Byers said that the difficulty in defining what was dysmenorrhœa arose from there being no way of measuring pain. For teaching purposes the well-known aphorism might be accepted that, among the leisured classes a woman could be said to suffer from dysmenorrhœa if the pain was so great that she could not fulfil her social duties, while among the poor they might be said to have dysmenorrhœa if they were unable to work. They might divide the cases seeking treatment into those without, and those with, local lesions, and the latter class, if any operative interference was to be done, must be managed with the very greatest care. He referred to the curious group of cases where the pain was not at the menstrual periods but midway between them and discussed their pathology.—Dr. Dempsey spoke of those cases in which the rheumatic diathesis seemed to be a factor in causation.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on May 9th, Dr. S. Buckley, the President, being in the chair.—Professor C. J. Wright (Leeds) showed a series of Plaster Casts illustrating the Effects of Birth Moulding in Various Presentations upon the Shape and Diameter of the Fœtal Head. The presenting parts shown were: (1) the occipito-anterior vertex; (2) the occipito-posterior vertex; (3) the head following pelvic presentation; (4) the face; (5) the brow; and (6) the vertex after delivery through a flattened pelvis. The models were obtained from Berlin for teaching purposes.—Other specimens were shown by Dr. J. B. Hellier (Leeds), Dr. J. E. Gemmell (Liverpool), Mr. H. Littlewood (Leeds), Dr. H. Briggs (Liverpool), and Dr. A. E. L. Wear (Leeds).—Dr. W. Murray Cairns (Liverpool) related a case in which he had performed Craniotomy and Cranioclasm for Face Presentation with Impaction in a Contracted Pelvis. The patient was pregnant for the tenth time, six of the previous labours having been difficult and instrumental. Dr. Cairns saw the case when labour had been in progress for 13 hours. The os was fully dilated, the face presenting, and the head impacted at the brim. The liquor amnii had already drained away. The forceps was applied and failed and version was found impossible. The head was perforated through the anterior fontanelle and extraction completed with the cranioclast. Dr. Cairns was of opinion that with the improved modern methods of performing Cæsarean section the treatment he had resorted to in this case would only be justifiable in very exceptional cases.—Dr. Cairns also mentioned a case of Intra-uterine Strangulation. An extremely neurotic patient, aged 32 years, in her first pregnancy suffered great discomfort from the tumultuous movements of the fœtus in utero. The symptom was alleviated somewhat by bromide of potassium. For several days before premature labour came on at the eighth month the movements had ceased to be felt. The fœtus when delivered had evidently been dead some days. The cord was very short and was drawn tightly round the child's neck. The skin of the neck was marked by the pressure of the constricting cord.—The cases were discussed by Dr. W. J. Sinclair, Mr. O. Roper, Dr. Briggs, Dr. Gemmell, and Dr. J. Braithwaite.—Dr. Hellier (Leeds) reported a case of Vaginal Hysterectomy in which Secondary Hæmorrhage occurred on the fifteenth day. The patient, a multipara, aged 51 years, was found to have early cancer of the cervix uteri. The growth was limited to the cervix and had not broken down much. The uterus was removed by vaginal hysterectomy, the operation being easy and not prolonged. Progress was good until the fourteenth day, when the last ligature came away and there was trifling bleeding. On the fifteenth day violent secondary arterial hæmorrhage came on which could not be controlled by vaginal packing. The patient, who was almost pulseless, was placed in the Trendelenburg position and the abdomen was opened. By means of Doyen's retractor and the electric light the bleeding point was seen to be a branch of the right ovarian artery. The vessel was tied and a gauze drain passed from the pelvis into the vagina. The patient made a good recovery.—The case was discussed by Dr. Sinclair, Dr. Briggs, Dr. Braithwaite, Mr. Littlewood, and Mr. S. Rumboll.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—A meeting of this society was held on May 9th, Mr. Lennox Browne, Vice-President, being in the chair.—Dr. Wyatt Wingrave read the notes of a case of Otomycosis (aspergillus niger) and showed a microscopical specimen of the fungus.—Mr. Mayo Collier exhibited a patient, a man, aged 63 years, suffering from Chorea of the Larynx of 12 months' duration, preceded by similar twitchings of the muscles of the face.—Dr. P. H. Abercrombie showed a case of Left Frontal Sinus Disease of 13 years' duration, with frequent attacks of excruciating pain and great tenderness over the right frontal sinus, which later, on exploration, was found to be healthy. Operation, three months ago, had resulted successfully.—Dr. Abercrombie also showed two new instruments (one by Dr. Jakins and the other his own) adapted to the Enlargement of the Fronto-nasal Canal.—Mr. Lennox Browne showed a patient, a man, aged 22 years, the subject since four years of age of Suppurative Median Otitis in the Left Ear. There was granulation tissue to be observed springing from the anterior and superior part of the tympanic cavity.—The discussion on Dr. Dundas Grant's paper on the Diagnosis and Treatment of the Various Forms of Nerve Deafness, read at the last meeting of the association, was resumed by Dr. Greville MacDonald who remarked that there were many peculiarities in patients the subjects of nerve deafness. For instance, many were extremely hypersensitive to loud sounds and were fond of quiet places; they were very deaf in noisy surroundings but heard pretty well when all else was quiet. To such loud noises were actually painful and in some cases might even induce giddiness. Such patients were extremely sensitive to syringing the ear and any sudden shock, such as flashes of light or the rapid passing of one of the red mail-carts, had been known to upset the equilibrium. Patients with nerve deafness were very liable to attacks of migraine (especially occipital) and this increased the deafness for two or three days. He thought that Dr. Grant's division into anæmic and congestive was valuable and was a good guide to treatment. Nevertheless, cases of anæmia were seen presenting signs of congestion of the internal ear, a state of matters no doubt attributable to vaso motor debility. Depletion was of value to both anæmic and congestive cases and an aperient was usually beneficial. He considered that the improvement in hearing, after many intra-nasal operations, such as depletion of the inferior turbinal or removal of septal spurs, could often be accounted for as much by depletion as by the removal of nasal obstruction.—Mr. Lennox Browne said that he agreed with Dr. MacDonald's remarks as to the explanation of the occurrence of both anæmia and congestion in the same patient, as well as in the value of depletion, but he could hardly agree that this latter alone explained the improvement in hearing, following the removal of intra-nasal obstruction. He thought that purgatives and restricted diet constituted a better basis of therapeutics than nerve tonics and nourishment. He had not seen any good result from the administration of quinine in nerve deafness.—Dr. Atwood Thorne, Dr. Wingrave, and Mr. W. J. C. Nourse also took part in the discussion.

West London Medico-Chirurgical Society.—The eighth meeting of the session (ordinary meeting) was held on May 2nd in the rooms of the Post-Graduate College, West London Hospital, Mr. McAdam Eccles, Vice-President, being in the chair.—Mr. Stephen Paget read a paper entitled "Notes on a Case of Empyema where Washing Out the Cavity was followed by Epileptiform Convulsions and Death." He referred also to other similar cases.—Dr. Seymour Taylor read a paper on Gall-Stones and their Medical Treatment, followed by Mr. L. A. Bidwell with a paper on Gall-Stones and their Surgical Treatment.—Mr. Alban Doran advocated the employment of prolonged incisions in operation on these cases.—Dr. O. Grünbaum commented on the comparative uselessness of oil in the treatment of gall-stones. He pointed out that an examination of the blood as to leucocytosis and the number of platelets might prove of great value in the diagnosis of the presence of pus in the gall-bladder.—Mr. Rickard W. Lloyd related particulars of two cases that had lately been under his care.—Mr. John R. Lunn read a paper on a case of Strangulated Femoral Hernia treated by herniotomy and followed by death in seven hours from collapse following the perforation of an ulcer just above the seat of strangulation.—Dr. Taylor and Mr. Paget commented upon the case.

Glasgow Southern Medical Society.—A meeting of this society was held on May 15th.—Through the kindness of Mr. W. Quarrier members had an opportunity of visiting the Consumption Sanatoriums at Bridge of Weir, Renfrewshire. There was a large attendance of the society and Mr. Quarrier personally conducted the party over the grounds and buildings. A close inspection was made of the more recently built sanatorium, given by friends in the East of Scotland, which is appropriately called "The Door of Hope." With regard to the treatment at the sanatoriums at Bridge of Weir it was pointed out that the method employed was similar to that known as the "Nordrach" treatment, consisting of an abundant supply of fresh air, generous diet, rest, and personal surveillance during residence. In all febrile cases rest in bed was strictly enjoined until the morning temperature was normal and the thermometer registered the evening temperature as less than a degree above the morning temperature. The average residence for those discharged reached 141 9 days and patients were admitted in all stages of the disease. The results were most encouraging and satisfactory.

Pathological Society of Manchester.—A meeting of this society was held on May 7th, Dr. H. Ashby, past-president, being in the chair.—Dr. Ashby showed a Medulla containing a Softened Patch from a case in which death was caused by respiratory paralysis.—Mr. W. P. Montgomery showed a specimen of Prostatic Adenomata removed by supra-pubic incision after the manner of so-called complete prostatectomy. The position of this operation was discussed.—Dr. F. C. Moore described Stenosis and Obliteration of the Large Hepatic Veins and showed specimens.—Mr. J. W. Smith and Dr. A. E. Finney mentioned a case of Contusion of the Abdomen resulting in Rupture of the Intestine and showed the specimens.

Reviews and Notices of Books.

Traité de Bactériologie Pure et Appliquée à la Médecine et à l'Hygiène. Par M. P. Miquel et M. R. Cambier, Directeur et Sous-directeur du Laboratoire de Bactériologie de la Ville de Paris. Paris: C. Naud. 1902. Pp. 1059. Price 45 francs.

This work is a most exhaustive treatise on bacteriology. It contains a more or less detailed digest of the most important researches carried out since the infancy of the science, and the book teems with copious references to the original literature, to which the student can have recourse for fuller knowledge on any special line of investigation. It is essentially a book of reference, not only on account of the authority which the names of the authors naturally lend to it, but also on account of the extensive range of its subject-matter, and as such it should appeal alike to the student of medicine, human or veterinary, of hygiene, or of pure bacteriology. Thus, while a considerable portion of the book is devoted to an account of the pathogenic bacteria, no less than 300 of the 1059 pages are taken up with descriptions of the non-pathogenic bacteria, such as those of fermentation, the chromogenic bacteria, and those found respectively in air, water, and soil.

The book is divided into four parts. The first part deals with the general properties of bacteria, morphological and biological, and with the methods of isolation, cultivation, and microscopical examination. The classification adopted is the usual morphological one—into micrococci, bacilli, and spirilla. The bactericidal properties of physical and chemical agents are very fully discussed and an interesting account is given of the variations which bacteria may undergo in form and in biological properties when acted upon by certain of these agents in varying degrees of intensity. It is satisfactory to note that the practice of interrupted sterilisation by heating to 100° C. for a short time on three successive days is condemned—a practice which we have reason to believe is much in vogue on this side of the Channel and of the inefficiency of which we have only lately had too good proof. The method is based on the false notion that the spores escaping one process of heating develop into the adult form during the 24-hours' interval

As a matter of fact, several days are required for the spores to recover their vitality after submission to the first heating. The method advocated here is sterilisation by the autoclave with a temperature of 110° to 111° C. for half an hour or filtration as an alternative for such cultivating media as do not admit of this treatment.

The second part is devoted to a detailed description of the pathogenic bacteria and the diseases of man and animal which are ascribed to them. Under "hæmorrhagic septicæmia" are described 11 different infections of animals by micrococci. Throughout this part of the work the diseases of animals due to known organisms are discussed in much detail; on the other hand, some of the human infections are not always treated at such length as their importance would seem to deserve. The attempts at immunisation against pneumonia, for instance, receive scant notice and the work of Washbourn is completely ignored No reference is made to Koch's views in regard to the differences between human and bovine tuberculosis and the inoculability of man with the latter The last chapter of this part, on Susceptibility and Immunity, is very brief. Ehrlich's chemical theory of toxins and antitoxins is not even mentioned. The whole subject is treated in a somewhat superficial manner. The diagnostic differences between pathogenic and closely similar non-pathogenic organisms, as in the case of the diphtheria and typhoid bacilli and the cholera spirilla, are most carefully described and support is given to the view that such organisms may have a close relationship—that a given organism may, under certain conditions, develop pathogenic properties and other biological variations and may relapse again into an innocuous state with change of those conditions.

The third part contains an account of the non-pathogenic bacteria. These are ranged under the headings of Zymogenic Bacteria, Chromogenic Bacteria, and Common, Saprogenic and Unclassified Bacteria. 12 different bacteria are described capable of transforming urea into ammonium carbonate and over 70 chromogenic bacteria are dealt with in this part.

The fourth part treats of bacteriology applied to hygiene. Here is heard the voice of authority in clear tones, and the methods of research adopted and developed by the authors in their investigation of bacterial contamination of air, water, and soil are given fully and make very interesting reading

The study of micromycetes and protozoa is not included in this work and consequently the malarial parasites do not find a place, but in the preface the authors express a hope to complete their treatise by a fifth part dealing with pathogenic and zymogenic infusoria and fungi.

Like so many books of this nature published on the continent, this work is issued in the form of a most cumbrous and inconvenient volume with a paper cover; the text, however, is printed in large type and on good paper.

Elements of Medicine. By ALFRED H CARTER, M.D. Lond., M.Sc. Birm. Eighth edition. London: H. K. Lewis. 1901. Pp. 590. Price 10s 6d.

IN the eighth edition of his "Elements of Medicine" Dr. Carter has strictly adhered to the style and method which have made the previous issues so peculiarly successful That is to say, it still remains a simple and straightforward introduction to the study of practical medicine which has caught the spirit of contemporary medical thought without in any way yielding to the passing fancies of our prolific specialisation or to the complicated nomenclature of our modern pathology. The present-day student of medicine, struggling with the encyclopædic information collected for his edification in up to-date text-books, will turn with relief to Dr. Carter's unsophisticated account of the diseases which he will meet with in practice. The whole of the text has been carefully revised and large portions have been entirely rewritten, while the section on Diseases of the Skin is from the pen of a new contributor—viz., Dr. W. d'Este Emery who has contributed a very readable chapter on his special subject. The section of the book which deals with general diseases and which includes an account of rheumatism, gout, diabetes, and cancer is very good, in particular the description of gout is a sound epitome of the symptoms of a perplexing disease. Dr. Carter's account of the predisposition to slow and perverted nitrogenous metabolism which characterises the nutritional processes of the gouty subject and the unfolding of his argument of the associated occurrence of obesity, diabetes, and gall-stones enable us to form a vivid picture of the essential nature of gout. One of the first conceptions, and often the only one, of the essential pathology of gout which dawns on the mental horizon of the average student is an image of a uric acid crystal deposited at a special seat of election—namely, the articular cartilage of the great toe. If he reads Dr. Carter he will appreciate that this deposition of uric acid is due to a relative over-taxation of nutrition associated with a gross or feeble habit of body and will be able to approach more elaborate works with a good chance of fully understanding them. Again, in his account of acute rheumatism Dr. Carter gives evidence of a nicely balanced judgment. While admitting that the essential nature of the disease still remains unknown he refuses to endorse the microbic theory. Throughout Dr. Carter views the power for good or evil which belongs to microbic organisms in a thoroughly rational perspective. The diseases of the nervous system have necessarily entailed a full share of revision and this work has been carefully and judiciously done. We notice, however, that no attempt has been made to bring locomotor ataxy and general paralysis of the insane into pathological line. Indeed, so far as the student will be able to gather from the two independent accounts of these conditions they do not possess a single feature in common. In the account of the muscular dystrophies, which are classified as primary and pseudo-hypertrophic, the author does not give us the impression of being perfectly clear in his own mind as to the relationship which these diseases hold to one another or to other muscular atrophies of undoubted nerve origin. The chapters which deal with the specific fevers and the diseases of the alimentary tract show fewer alterations than do those to which we have already referred. But taking the book all round it is certainly an improved as well as a revised edition of a useful text-book. It must not be used to supersede all the larger text-books. Dr. Carter proposes to treat of the "elements" of medicine and expects his work to be used more or less as an introduction to the comprehensive treatises.

Buller's Campaign with the Natal Field Force of 1900 By E. BLAKE KNOX, B.A., M D. Dub., Lieutenant, Royal Army Medical Corps. With Maps and Illustrations. London. R. Brimley Johnson. 1902. Pp. 336. Price 10s. 6d. net

WE may say at once that we closed this volume with the feeling that we had been reading a notable book. The author has the qualifications that go to make up a military historian. He has a discerning eye for taking in a military situation, and for seeing and describing the natural and topographical features and the dispositions of the belligerents on the scene of an engagement. Then he writes freshly, clearly, and to the point in describing what he sees and experiences and as to the impressions which the events—some of them terrible enough—create in his mind. The book, we are glad to notice, is dedicated to Colonel Sir Thomas J. Gallwey, K.C.M.G., C.B., R.A.M.C., the principal medical officer of the Natal army, and to its officers, as an expression of appreciation of the good comradeship that existed between all ranks during the campaign. Field medical arrangements and dispositions necessarily form part of the narrative and observations connected therewith are interspersed in the course of it, and a note on the medical aspect of the Natal campaign is added in an appendix. But the volume consists for the most part of the military history of that campaign.

The book begins with a very brief prologue of events preceding the arrival of the Fifth Division at Estcourt and the story of the battle of Colenso does not come into the narrative, but the author was present at all the engagements that followed, up to the relief of Ladysmith, and subsequently during General Buller's advance through Northern Natal into the Transvaal. He was one of those who witnessed the battle of Thaba Myama which culminated in the terrible struggle that occurred at Spion Kop. The description of the march to the Tugela in the first chapter strikes us as being well done. We may notice incidentally that the author points out how khaki drill when wet in the presence of a breeze acts as a refrigerator and that this fact having been appreciated the issue of serge was in later operations of the campaign substituted for khaki Chapters II. and III. deal with the battle of Thaba Myama and Spion Kop, and these chapters, comprising some 70 pages, are well worth reading, for the narrative is clear and vivid. Since the publication of this book—and since we began our review of it—the Spion Kop despatches have been published. It is a gloomy and painfully depressing, as well as a somewhat perplexing, story. The only redeeming point about it is the heroic conduct of the regimental officers and men and even the recognition of this is saddened by the feeling that all their efforts were rendered futile and unavailing from causes which we need not detail. As it happened, according to the author of this book, the Boers thought the withdrawal of our troops from the hill the worst mistake which we had made during the war. They were, in fact, retreating down one side while the Boers were going down the other.

The succeeding chapters narrate the battle of Vaal Krantz, the engagements round Colenso, Hart's Hill, and the final operations, including the battles of Pieter's Hill—which is excellently described—Laing's Nek, and Belfast. Throughout the volume the author dwells forcibly and emphatically upon the extraordinary difficulties and obstacles that had to be encountered and upon the stupendous nature of the task which fell to the lot of General Buller to undertake. Without expressly assuming to be a defender of General Buller it is nevertheless very clear that the author shared the devotion, personal loyalty, and confidence in their chief with which the soldiers of the Natal Field Force were inspired. It is quite refreshing and inspiriting to read what the author has to say about the courage and conduct of the troops and about the devoted services of the Indian bearers and the men of the stretcher corps.

Numerous descriptions, allusions, and comments relating to the officers and men of the Royal Army Medical Corps, the hospitals, and the wounded, and incidents connected with them, are interspersed in the text throughout the volume. If we were to refer to all the tempting passages and points which we had marked for notice our review would altogether exceed the limits at our disposal. The work to be rightly appreciated requires to be read as a continuous record of the operations of the Natal Field Force and as a whole; it is, we should add, capitally illustrated with plates and plans, and "well got up." We strongly recommend all who are interested in the subject to read it

LIBRARY TABLE.

The Way of Escape. By GRAHAM TRAVERS (Margaret G. Todd, M.D. Brux.). Edinburgh and London: William Blackwood and Sons. 1902. Pp. 383. Price 6*s.*—This work is on a higher plane even than "Windyhaugh," which was the previous work of Miss Todd. It is the story of a very noble life, and Vera is a woman whom any man would be proud to have the right to call his friend. Like so many other women, she wrecked her life for a man who was a cad and a coward, although he did not go about like some men of his kidney and talk about "my honour." Vera's fall, her rising again, her purgatorial life, and her triumphant end make up a very excellent novel. Miss Todd possesses the somewhat rare power of being able to write truthfully about children, a faculty which she owns in common with the author of "The Golden Age" and "Dream Days"—works which, we gather from a chance remark upon page 150, she knows and loves. If we were to pick a hole in "The Way of Escape" we should say that the story is somewhat *décousu*, but that is a common fault with writers who are treating a subject which they know intimately themselves for those who do not know. For instance, we are rather uncertain as to whether Vera had a baby or not, why she suddenly appears in Book II. as a governess in Brussels, and why towards the end of the book she should have felt compelled to tell her brother Harold all about herself. Miss Todd, of course, knows the answer to these questions; we have our own ideas on the subject, but we think that a little more accurate "joining of the flats" would have done no harm. Still the book is a fine piece of work and one which will still further increase Miss Todd's reputation.

JOURNALS AND MAGAZINES.

The Journal of Hygiene. Vol. II., No. 2, April, 1902. Cambridge: University Press. Price 5*s.* net.—This number opens with a paper by Surgeon Walter Reed of the United States Army upon the recent researches as to the Etiology, Propagation, and Prevention of Yellow Fever. The author was President of the United States Army Commission appointed to inquire into the subject and his testimony is therefore of much value. We have recently commented in our columns upon this matter and hence it suffices here to point out that the paper is of the greatest epidemiological interest and that it deals—destructively—with the bacteriology of yellow fever, that it brings out the important fact that yellow fever can be produced by the injection of a small quantity of bacteria-free serum filtrate obtained by passing the diluted serum through a Berkefeld filter. It deals, too, with the remarkable and heroic experiments by which it was shown that infected fomites were powerless to convey the disease and that the bites of infected *Stegomyia fasciata* alone were the means of conveying the disease. Finally, it recounts the steps taken to stamp out yellow fever in Havana, to which we alluded in our leading article of April 12th. Major C. Birt and Major W. B. Leisham, R.A.M.C., describe a new acid-fast streptothrix pathogenic to man and animals, and Captain Leonard Rogers, I.M.S., records his experiments as to the disinfection of floors for plague. He finds that very much stronger solutions are required to effect such disinfection than suffice to kill the plague bacillus in the test tube. Dr. D. Noel Paton furnishes the results of his observations on the movements of polluted water in the Tyne estuary. According to these observations—too few, as the author himself points out—the Tyne on the flood is relatively pure and allows the passage of salmon, there being no concentration zone of sewage as is the case in the Thames. Among other papers is one by Dr. G. S. Graham-Smith on the Measures taken to check Diphtheria at Colchester and one by Dr. George Dean and Dr. Charles Todd on their Experiments on the Relation of Cows to Diphtheria. The authors state in the beginning of their paper that there has been for many years an "impression" among sanitarians that milk is capable of acting as a vehicle of infection in scarlet fever. We should have inclined to the view that

4 per cent., of the deaths in these eight towns were not certified.

The annual rate of mortality in eight of the principal Scotch towns, which had been 23·6 and 23·7 per 1000 in the two preceding weeks, declined again to 20·3 per 1000 during the week ending March 29th, but exceeded by 2·1 per 1000 the mean rate during the same period in the 76 large English towns. Among these Scotch towns the death-rates ranged from 12·1 in Edinburgh and 14·1 in Perth to 25·8 in Leith and 28·4 in Aberdeen. The 655 deaths in these towns included 22 which resulted from diarrhœa, 14 from measles, 13 from whooping-cough, six from diphtheria, three from scarlet fever, and one from "fever." In all 59 deaths resulted from these principal zymotic diseases last week against 85 and 83 in the two preceding weeks. These 59 deaths were equal to an annual rate of 1·8 per 1000, which was 0·3 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 17, 23, and 25 in the three preceding weeks, declined again last week to 22, of which 11 occurred in Glasgow, three in Paisley, two in Dundee, two in Leith, and two in Greenock. The deaths from measles, which had decreased from 19 to 11 in the four preceding weeks, rose again to 14 last week, and included 12 in Glasgow. The fatal cases of whooping-cough, which had been 20, 23, and 28 in the three preceding weeks, declined again last week to 13, of which six were registered in Glasgow, four in Aberdeen, and two in Leith. The deaths from diphtheria, which had been seven, six, and four in the three preceding weeks, rose again to six last week, and included four in Glasgow, where two of the three fatal cases of scarlet fever were also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 230, 189, and 217 in the three preceding weeks, declined again last week to 173, but were 46 in excess of the number in the corresponding period of last year. The causes of 22, or more than 3 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 29·7 and 20·6 per 1000 in the two preceding weeks, rose again to 22·4 per 1000 during the week ending March 22nd. During the previous four weeks the death-rate has averaged 25·3 per 1000, the rates during the same period being 23·4 in London and 25·0 in Edinburgh. The 163 deaths of persons belonging to Dublin registered during the week under notice showed an increase of 13 over the number in the preceding week, and included six which were referred to the principal zymotic diseases, against 13 and eight in the two preceding weeks; of these, one was referred to each of the seven principal zymotic diseases, except small-pox. These six deaths were equal to an annual rate of 0·1 per 1000, the zymotic death-rates during the same period being 2·4 in London and 1·1 in Edinburgh. The mortality from measles and from scarlet fever was less than that recorded in the preceding week, while that from "fever" and from diarrhœa showed no variation. The 163 deaths in Dublin during the week included 25 of children under one year of age and 33 of persons aged upwards of 60 years; the deaths of infants showed a slight excess over the number in the preceding week, while those of elderly persons slightly declined. Five inquest cases and eight deaths from violence were registered; and 68, or more than one-third, of the deaths occurred in public institutions. The causes of eight, or nearly 5 per cent., of the deaths in Dublin were not certified.

The death-rate in Dublin, which had been 20·6 and 22·4 per 1000 in the two preceding weeks, further rose to 27·5 per 1000 during the week ending March 29th. During the 13 weeks of the quarter ending on that date the death-rate averaged 25·6 per 1000, the rates during the same period being 21·8 in London and 20·7 in Edinburgh. The 200 deaths of persons belonging to Dublin registered during the week under notice were 37 in excess of the number in the preceding week, and included seven which were referred to the principal zymotic diseases, against 13, eight, and six in the three preceding weeks; of these, two resulted from scarlet fever, two from whooping-cough, two from "fever," and one from measles. These seven deaths were equal to an annual rate of 1·0 per 1000, the zymotic death-rates during the same period being 2·6 in London and 0·2 in Edinburgh. The mortality from measles corresponded with that recorded in the preceding week, while that from scarlet fever, whooping-cough, and "fever," showed in each case a slight excess. The 200 deaths in Dublin last week included 30 of children under one year of age and 49 of persons aged upwards of 60 years; the deaths of infants and of elderly persons were respectively five and 16 above the numbers registered in the preceding week. Two inquest cases and one death from violence were reported, and 89, or nearly 45 per cent., of the deaths occurred in public institutions. The causes of 12, or 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

Royal Navy Medical Service.

Fleet Surgeon Robert William Anderson has been placed on the retired list of his rank. Dated Feb. 20th, 1902. Fleet Surgeon John Acheson has been placed on the retired list of his rank. Dated March 19th, 1902.

Imperial Yeomanry.

The undermentioned officers resign their commissions and receive new commissions subject to the provisions of the Militia and Yeomanry Act, 1901, each retaining his present rank and seniority.

Berks: Surgeon-Captain J. H. Waters. Royal 1st Devon: Surgeon-Lieutenant M. B. Steuart. Gloucestershire (Royal Gloucestershire Hussars): Surgeon Captain H. Bramwell. Lancashire Hussars: Surgeon-Major D. Harrison. Middlesex (Duke of Cambridge's Hussars) Supernumerary Surgeon-Captain (Honorary Major in the Army) C. Stonham, C.M.G. Northumberland (Hussars): Surgeon-Captain A. Brumell. Pembroke: Surgeon-Lieutenant-Colonel G. R. T. Phillips and Surgeon-Lieutenant J Wilson. Shropshire: Surgeon-Lieutenant-Colonel J. D. Lloyd. West Somerset: Surgeon-Lieutenant-Colonel S Farrant. Royal Wiltshire (Prince of Wales's Own Royal Regiment): Surgeon-Captain O. C. Maurice.

Volunteer Corps.

Royal Garrison Artillery (Volunteers):—Surgeon-Lieutenant D. L. Anderson resigns his commission. 3rd Middlesex: Charles Gordon Watson to be Surgeon-Lieutenant. *Rifle:* 3rd Volunteer Battalion the Norfolk Regiment: Surgeon-Captain C. R. Whitty to be Surgeon-Major; Surgeon-Lieutenant G. B. Masson to be Surgeon-Captain. 1st Volunteer Battalion the Duke of Cambridge's Own (Middlesex Regiment): The undermentioned Surgeon-Lieutenants to be Surgeon-Captains: W. N. Evans and G. A. Cohen. 2nd Volunteer Battalion the Manchester Regiment: Charles Christopher Heywood to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Durham Light Infantry: William Murray Mackay to be Surgeon-Lieutenant.

Royal Army Medical Corps (Volunteers).

The Woolwich Companies: Surgeon-Lieutenant-Colonel William Collingridge, late Militia Medical Staff Corps, to be Honorary Colonel.

Volunteer Infantry Brigade.

Leicester and Lincoln Surgeon-Lieutenant-Colonel R. B. Smith, 1st Volunteer Battalion the Leicestershire Regiment, to be Brigade Surgeon-Lieutenant-Colonel whilst holding the appointment of Senior Medical Officer to the Brigade. Sussex and Kent Surgeon-Lieutenant-Colonel T. Joyce, 2nd (the Weald of Kent) Volunteer Battalion the Buffs (East Kent Regiment), to be *Brigade-Surgeon-Lieutenant-Colonel* whilst holding the appointment of Senior Medical Officer to the Brigade.

India and the Indian Medical Services.

The King has approved of the following promotions among officers of the Indian Medical Service made by the Government of India:—To be Surgeon-General: Colonel Benjamin Franklin, K.H.P., C.I.E., Bengal Establishment.

The King has also approved of the retirement from the service of the under-mentioned officers: Lieutenant-Colonel William Owen, C.M.G., C.I.E., Bengal Establishment; and Lieutenant-Colonel Augustus Napoleon Rogers-Harrison, Madras Establishment.

South African War Notes.

Lieutenant-Colonel R. Jennings, R.A.M.C., Major C. G. Woods, R.A.M.C., Lieutenant J. F. Whelan, R.A.M.C., epidemiologically the connexion had been demonstrated, the only outstanding point being whether the disease in man ever has its origin in a disease of the cow. In the outbreak here in question there was an eruptive disease on the teats of the cows furnishing the milk and the diphtheria bacillus was found both on the eruption and in the milk. The authors, however, give reasons for inferring that the bacilli were superadded by the milker, albeit the evidence on this point is largely hypothetical. The eruption on the *cow's udders was not, the authors think*, cow-pox. The number concludes with an interesting review of the current theories regarding immunity from the pen of Dr. James Ritchie which should be most helpful to those who have been unable to follow the recent work step by step.

The Medical Journal of the Italian Navy.—The April number of the *Annali di Medicina Navale* contains several interesting articles, notably an illustrated synopsis of Dr. Lucas Championnière's work on the treatment of fractures by massage and passive movement, the illustrations being reproduced by special permission from the originals, and also, under the heading "Casuistica Clinica," the report by Dr. Giovanni Petella of a case of recurrent ophthalmoplegia which was under treatment in Professor C. Reymond's wards in the University of Turin. As usual, a considerable portion of the *Annali* is devoted to extracts from foreign medical journals, French, German, English, and American; but we have been unable to find anything having especial reference to naval medicine, surgery, or hygiene.

The *Medical Magazine* for May contains a pleasant and instructive article by Mr. S. B. Atkinson of the Inner Temple on the Law of Negligence in Relation to Medical Men. Mr. Atkinson deals with questions constantly arising the legal aspect of which is often most unfamiliar to medical men, for whom, nevertheless, such aspects may easily at any time acquire an intimate interest. In another contribution the new Royal Warrant for the Army Medical Service receives warm commendation at the hands of a retired medical officer who declares that the future position of the officers in the Royal Army Medical Corps will be decidedly an enviable one. The writer singles out particularly what he considers to be one weak point in the warrant—viz., the absence of all *evidence* that the India Office, *under the ægis* of which a certain period of service is almost invariably borne by young officers, intends to amend its conditions conformably with the improvements contemplated by the War Office. An extract from Dr. Claud Muirhead's report in connexion with the mortality experience of the Scottish Widows' Fund Assurance Society bears out the general notion as to the increase of cancer mortality and the comparative diminution of deaths from consumption.

# Analytical Records
FROM
THE LANCET LABORATORY.

BEEF KARNOID.

(THE KARNOID LABORATORY, CATERHAM, SURREY.)

WE have already commented favourably upon this preparation.[1] It is pulverised beef with simply the moisture removed by a cold-air process and the excess of fat eliminated. The beef is thus preserved in a raw state, containing myosin albumin in the same condition as in fresh-killed meat. The preparation has been further improved since we examined the specimens first submitted to us. This improvement is obvious from our recent analysis which was as follows: water, 6·66 per cent.; fat, 6 per cent.; mineral matter, 6·65 per cent.; and nitrogenous matter, 80·69 per cent. The total nitrogen amounted to 11·55 per cent. Over 27 per cent. of the beef powder is soluble in cold water and over one-third of this is meat albumin which coagulates on boiling the solution. The cold-water solution gives the spectrum of hæmoglobin. The preparation is one that may be confidently recommended, since in it are preserved unaltered the entire constituents of raw meat. From it a juice containing meat albumin or a nourishing soup may very readily be prepared. It is obviously far superior to the ordinary meat extract.

FRIEDRICHSHALL MINERAL WATER.

(C. OPPEL AND CO., 10 AND 12, MILTON STREET, LONDON, E.C.)

The Friedrichshall springs are situated in a charming valley in Saxe-Meiningen, Germany. The waters have long been known for their mild alterative and aperient properties which, as our analysis shows, are due to the presence of sulphates and chlorides of sodium and magnesium. Considering the mineralised nature of the water the taste is not so objectionable as might be supposed, owing probably to the preponderance of chlorides. Our analyses gave the following results expressed in grammes per litre: magnesium (Mg), 3·15; sodium (Na), 3·22; calcium (Ca), 1·00; sulphate (SO_4), 9·34 per cent.; and chloride (Cl), 8·69 per cent. The total saline constituents therefore amount to a little over 25 grammes per litre. Its aperient action is not drastic and a course of the water is unattended with objectionable results.

(1) PURGATIN; AND (2) TRIFERRIN.

(B. KUHN, 36, ST. MARY-AT-HILL, EASTCHEAP, LONDON, E.C.)

1. Purgatin is described as a derivative of the series of oxyanthra-quinones, a class of bodies to which belong the active constituents of such purging drugs as aloes, cascara sagrada, rhubarb, and senna. In appearance it is very like curry powder but uniformly crystalline. A dose as a mild laxative is from seven and a half to 15 grains, while if it is considered necessary as much as 30 grains may be administered without, it is stated, harmful results. Its administration produces a red discolouration of the urine due to the product of decomposition, anthra-purpurin, but the compound is said to be without irritation to the urinary organs. 2. Triferrin is the iron salt of nucleinic acid and therefore contains organic phosphorus. The proportion of iron is 22 per cent. and of phosphorus 2½ per cent. Triferrin is a brown rust-like powder which is not soluble in weak acids and hence it escapes the action of the stomach and passes into the intestines unchanged where it is absorbed. Clinical trial has shown that triferrin has a marked action in raising the proportion of hæmoglobin in the blood. It has no disturbing action upon the gastric organs, as have ordinary iron salts. Triferrin is a powerful hæmatenic.

(1) SOLUTION ADRENALIN CHLORIDE; (2) CASCARA EVACUANT; (3) ELIXIR GLYCERO PHOSPHATES; AND (4) THERMOFUGE.

(PARKE, DAVIS, AND CO., 111, QUEEN VICTORIA-STREET, LONDON, E.C.)

1. The physiological effect of adrenalin is now well known and it is also recognised that the solution adrenalin chloride is the most suitable form for administering the active principle of the suprarenal gland. We have referred already in our columns to the isolation of this active principle (adrenalin) and to the preparation of its chloride by the Japanese chemist Takamine. The preparation may prove useful in some cases in which the control of hæmorrhage or bleeding is a desideratum. 2. Cascara evacuant is described as an active preparation of the unchanged bitterless glucosides of cascara sagrada. It possesses a distinct laxative or purgative action, according to the dose employed, without any griping or disagreeable effects. The preparation is a dark-brown fluid which is somewhat strongly

---

[1] THE LANCET, June 1st, 1901.

aromatised. From 10 to 15 minims suffice for laxative purposes, while twice those quantities respectively are suggested when purgative effects are indicated. The agreeable taste is decidedly in favour of the preparation. 3. The elixir glycerophosphates is satisfactory as regards both purity and stability and contains the true salts of calcium and sodium. The indications for its use are well known. 4. Thermofuge is the basis of an excellent antiseptic poultice. It consists of a specially prepared clay worked into a paste with powerful and agreeable antiseptics. Its application promotes in the strictest sense cleanliness of the part to which it is to be applied whilst it is soothing and, as its name implies, antiphlogistic.

IRISH WHISKY.

(DUNVILLE AND CO., ROYAL IRISH DISTILLERIES, BELFAST, AND 239, SHAFTESBURY-AVENUE, LONDON, W.C.)

Two specimens submitted to us for examination proved to be good typical Irish whisky. The analysis of the "Special Reserve" was as follows: extractives, 0·20 per cent.; mineral matter, *nil;* alcohol, by weight 39·80 per cent., by volume 47·13 per cent., equal to proof spirit 82·59 per cent.; and acidity reckoned as acetic acid, 0·02 per cent. The specimen marked "V. R." gave the following results on analysis: extractives, 0 12 per cent.; mineral matter, *nil;* alcohol, by weight 40·30 per cent., by volume 47·67 per cent., equal to proof spirit 83·54 per cent.; acidity reckoned as acetic acid, 0·01 per cent. Both specimens were remarkably free from the ordinary impurities of whisky, they contained, practically speaking, no extractives and no sweetening matter, while they were without any appreciable degree of acidity. The flavour is characteristic of Irish whisky, "smooth," and delicately malty and the colour somewhat pale.

MALTOVA.

(THE MALTOVA FOOD CO., 11, NEW STATION-STREET, LEEDS.)

The combination of an active malt extract with raw eggs is an excellent idea. Such a preparation is calculated to contain all classes of material suited for the repair of the body waste. Moreover, the combination of course contains lecithin, that curious phosphorised principle of nerve substance, brain, &c. That maltova is a genuine preparation is obvious from the facts: (1) that it readily transforms starch into sugar, and (2) that it yields a coagulum of albumin on boiling. The preparation is one of undoubted merit and may be justly reckoned as belonging to the class of specially nutritious foods.

BANQUET CREAM.

(HERBERT FRANCIS AND CO., 8, ARTHUR-STREET WEST, LONDON, E.C.)

Though sterilised this cream on analysis presents a uniformity of composition. and its taste, while suggesting a "scalded" flavour, is quite acceptable. Our analysis was as follows: moisture, 62 81 per cent.; fat, 18·12 per cent.; curd, &c., 18·57 per cent.; and mineral matter, 0·50 per cent. We could trace no objectionable preservatives or any additions calculated to give consistence to the cream. The cream is in a liquid state and is suitable for all the purposes to which fresh cream is usually put.

THE ARMSTRONG BEEF AND MALT WINE.

(JAMES MURRAY AND SONS, 34, GREAT CLYDE-STREET, GLASGOW.)

We are prepared to bestow praise upon a wine which can be shown to contain any important amount of the nutrient matters of beef in solution. Never in our experience, however, have we met with such preparations, a fact which is hardly surprising since the nutritious portions of beef are incompatible with a fluid of the alcoholic strength of port wine. At most a solution of the beef extractives can be obtained and these are, as is well known, of little nutrient value. The analysis of the Armstrong beef and malt wine was as follows: extractives, 10·63 per cent.; alcohol, by weight 17·25 per cent., by volume 21·19 per cent., equal to proof spirit 37·13 per cent.; fixed acidity, calculated as tartaric acid, 0·33 per cent.; volatile acidity, calculated as acetic acid, 0·06 per cent.; and total nitrogen, 0·14 per cent. It is obvious from the total nitrogen that the wine contains practically no beef derivative. According to our experience the idea that beef can be combined serviceably with wine is a delusion. It would be better to recommend a glass of good port with an ordinary biscuit. A biscuit contains much more nutriment than it is possible to dissolve in a glass of port wine.

(1) TABLOID LIQUORICE COMPOUND POWDER; (2) TABLOID KINO COMPOUND POWDER; (3) SOLOID MICROSCOPIC STAINS; AND (4) SOLOID INDIGO TEST.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, LONDON, E.C.)

1. The tabloid liquorice compound is designed to meet the objection which patients exhibit to the ordinary powder. Each tabloid represents 30 grains of the compound liquorice powder. 2. A similar advantage is gained by the employment of the tabloid kino compound powder which besides is prepared with the purest drugs and may be relied upon to contain an accurate dose of the official preparation. The astringent properties of kino are well known, properties which have made it of service in the treatment of certain forms of diarrhœa and dysentery. 3. The convenience of possessing in the clinical laboratory a series of microscopic stains in soloid form is obvious since the soloid presents at once a standard amount of dye for preparing an aqueous or alcoholic solution. Time is saved and a solution in accordance with requirements is readily obtained. Since the soloids are prepared with dyes of ascertained purity much trouble is avoided and good uniform results are obtained, while their adoption dispenses with the necessity of keeping a stock solution in which state the dye is apt to deteriorate. 4. The soloid indigo test facilitates the detection of sugar in urine by the sodium nitrophenylpropiolate reaction. 10 mimins of the urine are mixed with three drachms of water. One soloid is next added and the liquid is boiled. In the presence of glucose the liquid will assume a blue colour owing to the formation of indigo. An important advantage of this test is that the reaction is not influenced by uric acid, creatinine, glycuronic acid, bile colouring, or by substances which may be contained in the urine after the administration of certain drugs.

SALUVINO CORDIAL.

(THE STANDARD WINE ASSOCIATION, 19, ST. DUNSTAN'S-HILL, LONDON, E C.)

This is a somewhat sweet red wine with a peculiar aromatic flavour. The wine basis is said to be red Médoc. On analysis we obtained the following results: alcohol, by weight 15·67 per cent., by volume 19·28 per cent., equal to proof spirit 33·79 per cent.; extractives, 18·13 per cent.; mineral matter, 0·16 per cent.; fixed acid, calculated as tartaric acid, 0·25 per cent.; volatile acid, calculated as acetic acid, 0·09 per cent.; and sugar, 7·7 per cent. As will be seen, the wine shows the alcoholic strength of port wine. "Saluvino" is an agreeable stimulant and cordial and is of some value as a tonic, such value being referable, amongst other things, to iron and certain aromatics and bitters.

DIGESTIVE LENTIL FLOUR.

(THE DIGESTIVE FOOD CO., PAISLEY.)

Lentil flour has been justly described as the beef of the vegetable kingdom owing to its high proportion of proteid. The sample before us has been specially prepared with a view to raise its digestibility. One effect of this preparation, according to our analysis, has been to increase the solubility of the flour. Thus, on shaking up with cold water and filtering the liquid it will be found to yield a distinct coagulum on adding alcohol. Analysis gave the following results: moisture, 7·90 per cent.; proteid, 29·92 per cent.; and mineral matter, 2·60 per cent., containing a notable quantity of phosphates. It will be seen that besides a remarkable proportion of proteids the lentil flour contains also a relatively large amount of mineral salts of dietetic importance. The "digestive lentil flour" may be recommended.

THE LANCET.

LONDON: SATURDAY, MAY 24, 1902.

Feeble-minded Persons and Crime.

THE fact is now generally recognised that an appreciable number of men and women are feeble-minded owing to congenital deficiency without being either imbecile or insane. The larger proportion of these persons are males, of whom some tend towards dependency from want of power to support and to protect themselves, while others tend to lead criminal lives or to become themselves the prey of crime. Among the poorer classes many such persons, being without resources of their own and unprotected, fall to vagrancy and pauperism. In the wealthier sections of society the men fail to take any useful or creditable position, and the women if married lead most unhappy lives and become the mothers of children feeble like themselves. Elsewhere we publish a paper by Miss DENDY, an active member of the Manchester School Board, giving the social history of many feeble-minded persons as ascertained by careful personal inquiry. The reports on their mental defectiveness have been verified by Dr. HENRY ASHBY and Dr. G. E. SHUTTLEWORTH and the facts given show plainly the strong tendency of persons mentally feeble to fall into a state of pauperism and crime if left friendless, untrained, and unprotected.

There is ample evidence, to which Miss DENDY's paper further contributes, to show that the offspring of feeble-minded persons, both men and women, usually inherit their defectiveness in some degree and that in this way the evil is perpetuated. But the inheritance of mental deficiency from one or both parents is not the only cause of the condition, and it is not safe to consider imbecility on a mere question of heredity. It is not uncommon to meet with examples where both the father and the mother of a feeble-minded child are above the average development of their respective families in mental ability, and a single case of defect among several intelligent brothers and sisters is often to be found; in fact, when there is marked evolution in a family there is often one instance of decadence, such misfortune appearing more often among the sons and frequently in the case of the eldest. Cases of congenital defect are more common among males, many of whom die in their first year, thus adding to the cases of infant mortality; and it is noticed that while the larger proportion of children born are males, after the first year girls predominate in numbers. Surviving cases of congenital defect form the subjects of grave social problems, for, uncared for and untrained, they tend to increase the criminal and pauper sections of our population. Special classes of instruction under the Defective and Epileptic Children Act provide day-school training for these unfortunate children up to 16 years of age, and a few educational homes have been established for the reception of children. There is no doubt an increasing feeling that more should be done for these helpless little ones. The Lancashire and Cheshire Society for the Permanent Care of the Feeble-minded desires to found homes wherein cases that require continued protection may be received. We wish the society success in this work which may transform children apparently only a burden to themselves and the social scheme into more or less useful citizens. After several years of carefully planned training during school age feeble-minded children may be educated to be decent and self-helpful; intelligent speech and habits of orderliness and obedience can be acquired under control; moreover, their actions, movements, powers of seeing and of thinking may be *cultivated up to the full brain capacity of the individual* and thus their lives may be made happy and good. Defective brains may be much improved. Medical men of course know this, but we are laying a little stress on the fact here, as we hope that our readers will constitute themselves, when opportunity serves, the champions of the feeble-minded child. It is necessary to assure the public that the money required for the systematic training of these children is not thrown away. We do not attempt to deny that defective brains are always liable to lose the mental acquisitions gained under training. This, however, is not the case so much if the mind is kept alive by exercise. When the feeble-minded undertake industrial work they need to be taught to perform each process carefully and *methodically, stage by stage, so that by practice they may* be enabled to accomplish something towards their maintenance. Homes in which such graduated and well-ordered instruction can be given can never be really *self-supporting*, but they are greatly needed to save many women and men from a life of degradation.

The number of individuals who require this systematic attention from their early youth is undoubtedly large, but we think that Miss DENDY has put the figure too high. She states that "2 per cent. at least of our school-going population are in some degree weak-minded." The Departmental Committee of the Educational Board on Defective and Epileptic Children reports that "approximately 1 per cent. of the children of the public elementary school class appear to be feeble-minded." Dr. FRANCIS WARNER in his evidence before that committee stated that among 100,000 children he found 930 mentally deficient, but the schools which were examined included many under the Poor Law and Home Office where the percentage of feeble-minded *is higher than in elementary schools*. Among public elementary schools with 86,000 children actually in attendance (1892-94) 0·65 per cent. were stated, by the same observer to be feeble-minded. As a matter of fact a great deal of discrimination is required in order to ascertain these figures *with irreproachable accuracy*. Among 100 cases collected by teachers and visitors as "exceptional cases" and examined for the Charity Organisation Society Dr. WARNER reported 32 cases as "not exceptional,"[1] a fact which indicates that careful examination and diagnosis of feeble-minded children are necessary in all schemes designed for their care. The Elementary (Defective and Epileptic Children) Act, 1899, provides that "for the purposes of ascertaining whether a child is defective or epileptic within the meaning of this section, a certificate to that effect by a duly qualified practitioner approved by the Education Department shall be required in each case. The certificate shall be in such form as may be prescribed by the Education Department."

◆

What is a "Cure"?

MEDICINE presents many problems to her faithful followers. One, however, may fairly be considered to be the greatest of them all, whether on account of the extreme difficulty offered to its solution or because of the fact that it arises in connexion with almost every case that the physician treats. This problem is to decide how far the effects of given therapeutic measures have resulted in a "cure"—a word that the medical man, knowing its full significance, seldom employs without reservation. It often enough occurs, happily, that treatment is given and disease disappears. How often can the medical man say with certainty that the disappearance is due to the remedy, that without it the disease would have persisted, and that nature could not quite as well have effected alone what medicine has accomplished with her aid? This question which must constantly recur to every thoughtful practitioner has formed the theme of a presidential address recently delivered in the Section of Medicine of the Intercolonial Congress of Australasia by Dr. JAMES JAMIESON, lecturer on medicine in the University of Melbourne. In Dr. JAMIESON'S address the crux of the question discussed was not, as might possibly be surmised, the temporary or permanent nature of the changes regarded as cure but whether this change is always simply brought about by nature's undoubted beneficent processes or whether therapeutic measures do considerably help, modify, or even actually cause these processes. The answer of modern medical opinion to the question, "Can we cure?" partakes strongly of the nature of modified scepticism. Medicine labours to be scientific and the essence of science is a sceptical attitude towards the unproven. It is the proof of real effects that is so hard to substantiate in the matter of therapeutics. Consequently medical men of scientific training necessarily start with a sceptical attitude even towards the results that they themselves apparently have achieved.

This attitude, however, as Dr. JAMIESON points out, is a comparatively new one among practitioners of medicine. Until the time came when medicine was founded on science medical men shared with the general public a blindly trusting faith in the efficacy of all kinds of empirical remedies. Not until the beginning of rational scientific medicine did it occur to men to doubt whether an illness which was recovered from when certain drugs had been administered could have righted itself without these medicines. Such doubts arise directly the administrator of drugs has an insight into the physiological working of the machine the disorders of which he seeks to rectify. Beholding the complexity, the adaptability, and the various nature of the component systems of the human organism he suspects in it an almost infinite capacity for readjusting disordered processes or for expelling injurious influences. Thus he is led away from a vigorous, often harmful, empiricism into a watchful, perhaps even a timid, attitude in the treatment of disease. According to Dr. JAMIESON, the physician's scepticism as to the potency of drugs is still quite unshared by laymen who, if they often blame a medical man for failure that is unavoidable, perhaps equally often give him credit for results due entirely to the operations of nature. It is not surprising that the ordinary individual should be slow to change his faith in the unerring efficacy of drugs when we remember that it is really only within the last hundred years or so that medical men have given up an equally rooted belief, the cherished tradition of centuries. Yet, further back still, in the time of HIPPOCRATES, we find a view of disease that is as rational if not so fully informed as that of the most cultured physicians of to-day. HIPPOCRATES scouted the notion that any disease came as an affliction from the gods and declared that all illness had its origin in natural causes. He laid great stress upon prognosis, which can be safely founded only upon a knowledge of the natural course of disease. Followers in the footsteps of HIPPOCRATES doubtless there have been among physicians in all ages, but till at least the early part of last century the medical mind, as a whole, was deeply, and honestly, impressed with the power of therapeutic measures to determine the course, and actually to bring about the cure, of all diseases. To-day we are obliged to regard as at present unknown the really curative agents for very many disorders, but happily together with this well-founded scepticism of therapeutic effect in many cases we have justified ourselves in the use of drugs and of therapeutic measures in other instances where the undoubted benefits that these bring are based upon a sure and scientific understanding of the etiology and pathology of the conditions successfully treated. Antitoxin in diphtheria, thyroid gland in myxœdema, and the nitrites in angina pectoris, are only some of the fruits of the scientific study of medicine that we may name in support of the well-founded, if limited, therapeutic faith that replaces in the mind of a modern practitioner the wide but ignorant credulity of his predecessors.

An interesting passage in the address which has inspired these remarks points out how the rise of homœopathy, mistaken though its tenets are, helped in the destruction of a blind faith in the curative powers of drugs. It was not that HAHNEMANN himself was sceptical but those who could not accept the fundamental doctrines of homœopathy, or its peculiar mode of practice, were at any rate obliged to admit that results equal to those from their own practice often attended a method of treatment which was tantamount to giving no drugs at all. Thus, inquiry was naturally stimulated as to the course of disease if untreated and as to the actual effect or importance of medicines hitherto regarded unhesitatingly as actively beneficial. The best physicians felt that very likely they could not do much in the way of directly curing disease and that the first thing was to try to understand it. Thus followed a general return to the Hippocratic standpoint. Men saw that they could not tell with any approach to certainty what the effect of treatment was, or might be, if they could not predict what the progress of a case would have been had the patient remained untreated. Upon an open-minded observation of disease follows some understanding of the means and processes by which nature contrives recovery. Disease is seen to be a disturbance of physiological processes. As the organism is subject to constant changes so diseases, too, to a greater or less extent, suffer variations. It is this variability, Dr JAMIESON points out, this constant waste and renovation of body-structures, that makes recovery or cure possible. It may have had a manifest external cause, but in its essence disease is only a modification of natural processes, and cure must be accomplished by similar processes. To say this is not to declare that art cannot intervene and by removing injurious influences give that turn to natural processes which determines the occurrence of cure. But it is only by knowing nature's own method of cure that we can find rational basis for our therapeutic endeavours. The first of these natural processes would seem to be removal of the cause of the disease. It often happens, *though, that*, the primary cause ceasing to act, the disease still continues. This may be through the evil intervention of other causes the influence of which the state of the organism induced by the primary cause has made potent. It is particularly in the recognition of these secondary causes and in the discovery of methods for removing and controlling them that modern medicine has made progress and is hopeful of still wider conquests.

The discovery of the bacterial origin of infective diseases must be regarded as a fine example of the recognition of cause in disease. Together with the constant endeavour to trace cause must go the physician's unwearying effort to recognise the signs of nature's own curative efforts. Otherwise he will find himself combating symptoms that are a necessary accompaniment of reparative processes. Moreover, without such observation of natural progress to recovery no imitation of natural repair can be intelligently instituted. Dr JAMIESON in his excellent address shows how such observation has in several instances made successful imitation of natural cure possible and his words leave us convinced that the modern scientific sceptical attitude towards remedies in general has already led to therapeutic discoveries of the highest importance and benefit and should *give us confident hope that more diseases will in the near* future come within the range of a rational system of healing.

◆

The Etiology of Typhoid Fever.

THERE are certain factors in relation to the etiology of typhoid fever which are now generally accepted as proved but in regard to others much difference of opinion and doubt still exist. That the organism first described by EBERTH holds a direct causal relationship to the disease is certain, although some of its characteristics and properties are still under investigation. Water is universally recognised as the medium through which the disease is most commonly and extensively spread but there are undoubtedly other means by which the disease may be contracted which are less recognised. Dr W. H. CORFIELD[1] in the Milroy Lectures which he recently delivered at the Royal College of Physicians of London gave an elaborate historical account of *typhoid fever*, full of interest as showing the various phases of thought through which medical observers have passed at different periods during the progress of medical science. He brought his survey up to the most recent times, thus presenting the profession with a most valuable *résumé* of the work which has been accomplished with reference to the origin and mode of spread of typhoid fever. Dr THOMAS CHERRY[2] in an address delivered before the sixth session of the International Medical Congress of Australasia, held at Hobart in February of this year, also made some interesting remarks on the same subject.

For the purposes of prophylaxis it is, of course, of the utmost importance to ascertain the length of time during which the typhoid bacillus may remain in the tissues of the body while still retaining its potential infectivity and *also the conditions under which the bacillus can exist outside the body*. Both the lecturers above mentioned referred to observations which had been made in order to obtain information on these points. Dr P. HORTON SMITH[3] in the Goulstonian Lectures delivered before the Royal College of Physicians of London in 1900 quoted cases in which it had been proved that the typhoid bacillus persisted in the body, especially in the bile, for three months *after the fever in one instance*, in another case for eight months, and in a third case after an interval of seven years. The most remarkable case of all, however, and one very carefully tested, is that recorded by Dr VON DUNGERN in which, fourteen and a half years after the attack of the fever, the bacilli were still present in pure culture "in the pus." Dr SIDNEY H. C. MARTIN found that the bacillus, when implanted in *organically polluted soil*, "*speedily increased and spread* abroad," whereas in an unpolluted soil from an uninhabited and uncultivated area "it languished and quickly died out" under like conditions of temperature and moisture. One of Dr MARTIN's most important conclusions is that the soils which are favourable to the growth of the typhoid bacillus are those which have been cultivated—more particularly *soils of gardens and the entourage of houses*. In these soils the bacillus was found to be alive and to have retained its vegetative properties for as long as 456 days, this being found true for sterilised soil which was moistened throughout with water. On drying this soil, even when it had become so dry that it could be made into a fine powder, the bacillus could still be obtained from it and had retained its vegetative properties. Virgin soils, sandy or peaty, were found to be absolutely inimical to the growth of the organism. Dr CHERRY quotes a case reported by Dr P. H. METCALFE which occurred in Norfolk Island (lying 1100 miles from both New South Wales and New Zealand). In 1863 there had been an epidemic "of some kind of fever" on the island. No further cases occurred till 1877 when a man was reported to have died from fever. In January, 1860, a typical case of typhoid fever occurred at the mission station in a man who had arrived in the island in the previous September. On investigation it was found that he was the only person in the island who drank the water from a well with a bad reputation. Dr. METCALFE thought that only two hypotheses to account for the fever were possible—either that the patient carried the contagion with him for fifteen months (i.e., since he left England) or else that the disease originated *de novo*. Dr. CHERRY adds three other suggestions, which he admits are all very difficult of acceptance: (1) that the typhoid bacillus may have been in the polluted well for several years; (2) that some of the islanders had been carrying it about in their bladders or intestines for a similar period; or (3) that the attack was caused by Gärtner's bacillus which existed in the well. Dr. CORFIELD and Dr. CHERRY further refer at some length to the various channels by means of which the fever may be spread. They both agree that water, milk, and food are chiefly to blame for its dissemination, but that in hot countries, at least, flies and dust have a considerable share in bringing about this contamination. Dr. CORFIELD also refers to a discussion which took place at the Epidemiological Society in 1900 in which, from the remarks of the different speakers, it was evident that there was great unanimity of opinion, not only among the inspectors of the Local Government Board but among medical officers of health throughout the country, that communication by direct contagion is a much more common cause of spread of typhoid fever than is generally supposed.

[3] THE LANCET, March 24th (p. 821) and 31st (p. 910) and April 14th (p. 1060), 1900.

The above considerations suggest many indications as to the basis upon which preventive measures against typhoid fever should be founded. To quote the words of Dr. HORTON-SMITH: "Truly no longer can we say with Dr. BUDD that 'by destroying the infectious power of the intestinal discharges the disease may be in time finally extinguished.' So far, indeed, from the stools being the only agents by means of which the disease is spread, they are but one of a series of agents. So far, too, from the patient ceasing to be a source of danger after his restoration to seeming health, he may carry about in himself the seeds of infection for months and even years." Many public improvements in towns and country districts have coincided with a reduction in the prevalence of typhoid fever, such as the drying of the soil, reduction in the crowding of houses, and the substitution of an ample supply of good water for a scanty and impure supply. It is, however, as the late Sir GEORGE BUCHANAN pointed out, the purification of the atmosphere from decomposing organic matters that has been most uniformly followed by a fall in the prevalence of typhoid fever. This fact would bear out the suggestions that have been made as to the etiology of the disease which we have been considering—that although water is the most common medium for conveyance of the pathogenic bacillus yet other sources of contagion occasionally play a part, and it is therefore necessary to take all precautions to ensure not only that the water-supply of a town or district is pure but also that the disposal of sewage and waste organic matters of every kind is properly provided for.

CHELTENHAM GENERAL HOSPITAL.—The committee of the Cheltenham General Hospital has had the offer of an anonymous gift of £1000 to endow a bed subject to the condition that no anti-vaccinationist should be eligible to occupy it.

Annotations.

"Ne quid nimis."

FUSS AS A MARK OF MODERN CIVILISATION.

EVEN the dry text of a Parliamentary paper may afford material of more than purely political interest. The recently published report of the Committee on Shipbuilding for the Navy contains a suggestion which we cannot pass over without comment. It is that in which Sir Francis Evans condemns the present system of inspection in detail, a minute and vexatious process, and maintains that contractors of character and position should be frankly taken into the confidence of the Government and allowed a reasonable latitude and initiative as its collaborators in the national interest. There is an obvious good sense about this proposal which cannot be seriously discounted unless we are to admit a practical failure of intelligence and of commercial probity among the heads of a most important and peculiarly British industry. But the subject with which it deals is wider than any one field of manufacturing activity. Whatever the work to be done unnecessarily close inspection is more likely to act as a cause of obstruction and delay than as a stimulus to success. Where such intervention is official it is usually far from unintelligent but if needless and untimely it may do harm nevertheless. It is refreshing in these days of nervous overzeal to find a Parliamentary committee that is candid enough to admit this. There are other cases where supervision is gratuitous and irresponsible and can claim no excuse either in the obligations of office or in the possession of special knowledge. In such cases it is as far removed from intelligent criticism as it is nearly allied to meddlesome curiosity. It is to this kind of investigation that medical practice is at times particularly liable. A distinguished person is ill and forthwith every incident in his condition is focussed by industrious interviewers as if they acted for a jury of physicians. All that his countrymen wish to know is whether he is better or not. In addition to information on this all-important point they are treated to minute details of pulse, respiration, temperature, drugs, and perhaps of something approaching to sick-room gossip as well. Meanwhile his attendants, evidently not having enough on their hands already, are liable to be pestered with suggestions for treatment derived from all imaginable sources. All this does not make for recovery. Much the same thing happens when there is news of a reverse at the seat of war. We have only to invert the telescope in order to find the civilian from his writing-table at home carefully endeavouring to instruct the soldier in his duties regardless alike of military methods and of local conditions. Other examples of a like nature might be quoted but the foregoing will suffice to direct attention to a quality of mind which appears to be increasingly prevalent among a certain class of writers and talkers and which cannot be regarded as a sign of healthy social life. It is not vigilance or prudence or deliberate and considered judgment; it is not even a natural and rational anxiety, though it may exhibit itself in the guise of any one of these. It is mere fussiness. Serving in itself no profitable purpose, it mingles with and impedes every useful work, damping energy and discouraging initiative and the sense of responsibility in those engaged in it. All the while it may be preaching moderation, patience, and self-control. This neurosis is not confined to any people or part of the civilised world, though it seems to be more prevalent in some quarters than elsewhere. Wherever there exists a suitable soil in the form of an intellect equipped with the visual organs of education but without corresponding reflective power and self restraint there the morbid germ develops until it may even become epidemic over a wide area. We have already noticed some of its manifestations and have referred to the instability of will and the incoördinated action which are its natural consequences. In these circumstances its effective treatment is obviously most desirable. Fortunately it is a true functional disorder and there is no reason to regard it as incurable. If only the exciting cause be frankly recognised and grappled with much will have been done towards providing a remedy In order to arrive at a successful result, however, it is necessary to begin by admitting that scrutiny in technical matters, even by those whom it may concern, may be overdone. It matters little whether it be carried out by a subordinate Government official, by an over zealous pressman, or by a private individual more eager than judicious, if superfluous the effect is the same. To let well alone is an axiom synonymous with sound practice. To say that details of matters not belonging to the province of common knowledge should be left in the hands of selected and competent persons is another way of expressing the same truth. The contrary method, that of prying and open mouthed publicity, is incompatible with successful business, with the public service, and with the very desirable extinction of the alarmist neurosis.

NICETIES OF NURSING.

THAT a good nurse must have other qualities besides a sufficient knowledge of, and skill in, her profession is as plain to all who have had the misfortune of being "patients" as it is that similar advantages are necessary in a medical man if he is to be, not only a safe, but also a welcome, adviser For a nurse, indeed, these qualities, which we may take to be tact, sympathy, and the knack of doing the right thing with the least possible unpleasantness, are even more essential than they are in the practitioner s case, for he sees comparatively little of his patients, while the nurse is to a large extent constantly present. The modern nurse is such a vast improvement professionally upon her predecessor and her position in the sick room and in the hospital is so well established and generally so well filled that she is apt to overlook or to forget the great importance of being pleasant and considerate as well as professionally accomplished. The old fashioned nurse was of very little benefit to her patient in illness and the modern nurse seems sometimes to imagine that it is for her benefit that the patient is ill. She demands sometimes little attentions and consideration which really it is her duty to supply It is particularly, of course, in private houses that a selfish or a thoughtless nurse can make her presence a necessary evil instead of being a grateful source of ease to her patient. Many of the little extra points by attention to which a nurse can multiply many times the gratitude of those in her charge are given in an address on the "Little Niceties of Private Nursing" by Mrs. Emily F Stewart Brown, lady president of the Liverpool Hospital for Women. The address contains, moreover, some directions bearing upon small points in a nurse's actual duties of much importance but often neglected in private nursing where the conveniences of a hospital and the watchful eye of a superior may be alike absent. Mrs. Stewart Brown's advice is contained in a series of "Don'ts" and is based upon true instances. We pity the patient whose experience of nursing provided Mrs. Stewart Brown with this succinct prohibition, "Don't cultivate a love for the succulent onion." A wise injunction to nurses engaged in private houses is "Don't forget that illness upsets the routine of a household, and make things as pleasant as you can; if you don't your meals will be anything but elaborate and the attention you will receive very limited." Mrs. Stewart Brown is not in her address concerned with the other side of the question, or we can well imagine a series of "Don'ts" applicable to people who employ nurses and who are sometimes strangely inconsiderate in what they expect at a nurse s hands Sometimes there is a tendency to overlook the fact that a nurse needs food, sleep, and some comfort even as ordinary persons do—still more than other folks, perhaps, when engaged upon an arduous case To very many nurses, we are glad to know, most of Mrs Stewart Brown s prohibitions are superfluous, by none, however, can they be read with anything but pleasure and by most, we are sure, with very great advantage.

SUCCESSFUL TREATMENT OF PARENTAL NEGLECT.

REFORMATION rather than punishment has always been the aim of the National Society for the Prevention of Cruelty to Children. It affords protection to helpless children but it does more than this. It endeavours to awaken, if possible, in defaulting parents a desire to do likewise. Two cases mentioned in a recent issue of the society's periodical go to prove that its efforts in this direction have not been altogether unsuccessful In each instance a drunken mother had grossly neglected her duties to her family and had been sentenced to a term of imprisonment. Both women after their liberation abandoned the drinking habit, became industrious, maintained their children in sobriety and comfort, and eventually returned to thank the agents of the society for what it had done for them This, we are assured, is the kind of work which is being carried on throughout the country We believe the statement though we are also alive to the fact that actual punishment is not lightly resorted to. These cases are their own commentary They show that a penalty when judiciously employed may and does act as a stimulus to the parental sense of responsibility There must be few persons who do not join us in the hope that such work may continue.

THE THERAPEUTICS OF THE X RAYS

THE value of the light treatment in lupus and in certain cases of superficial malignant disease, particularly rodent ulcer, is now established But the permanency of the "cures" which have been obtained and the utility of the treatment in other forms of malignant disease and in other diseases remain to be determined. In the *Journal of the American Medical Association* of April 12th Dr Allen Pusey, professor of dermatology in the University of Illinois, has published a well reasoned paper which tends to show that the field of utility of the x rays is greater than that in which they have been employed in this country He describes 36 cases of various diseases, principally malignant, and gives 24 excellent illustrations showing the condition before and after treatment. His results therefore cannot be gainsaid. In lupus they are simply confirmatory the x rays cause the disease to disappear and yield white, soft, pliable scars which could not be less extensive under any other method. Even in the case in which the longest interval—18 months—had elapsed since recovery there was no sign of recurrence. Eight consecutive cases of "epithelioma" (most, if not all, of them appear to be cases which in England would be termed "rodent ulcer") were treated successfully, the ulcer being replaced by healthy scar One case "was beyond relief by any other method" and Dr Pusey with pardonable pride claims it as "unique" A man, aged 35 years, came under treatment. 11 years before a small nodule appeared on the right cheek below the eye. It gradually enlarged and after two years it ulcerated. Five years later a radical operation was performed; the ulcer and a large amount of the surrounding tissue were removed. The lower eyelid had to be restored by an extensive plastic operation. After a year recurrence took place and the orbit became involved. The disease was so extensive that a surgeon would not operate. The entire orbit, both eyelids, the side of the nose and the cheek were involved. The eyeball was shrunken and retracted in the orbit. Microscopical examination confirmed the diagnosis of epithelioma. The eyeball was removed but this did not relieve the severe pain. Exposures to the x rays were given almost daily until erythema and slight desquamation were produced. Within a week the pain ceased and the discharge diminished. The borders and the nodules shrank and the ulcer began to heal. The surrounding tissue became smooth, soft, moveable, and free from induration. After three months the ulcer was almost healed and the patient had regained health. Sections of the border of the ulcer made before and after the exposures demonstrated the effect of the treatment: the abundant downgrowth of epithelium was replaced by a degenerated, structureless, wavy substance. A very similar case has recently been recorded by Dr. G. Stopford Taylor.[1] In three cases of recurrent cancer of the breast remarkable benefit was obtained. Thus in one case the skin and subcutaneous tissue for an area six inches in diameter round the scar were infiltrated with cancer and there were ulcerating nodules. Four months after the treatment was begun all traces of cancer had disappeared. In three other cases, however, the treatment failed. In lymphadenoma exposure of enlarged glands to the x rays was followed by almost complete subsidence and improvement in the general condition—for example, the hæmoglobin in the blood increased from 50 per cent. of the normal to 80 per cent. Of course, the question whether the improvement in all these cases will remain permanent cannot yet be answered. But even if it does not the striking benefit obtained in the inoperable cases of cancer is sufficient to make the light treatment a valuable addition to therapeutics. Moreover, in case of recurrence it may yield in turn to the same treatment. Dr. Pusey's paper is all the more valuable because he does not attempt to claim too much. He points out that the advantages of the x-ray treatment are: (1) that it is painless; (2) that it destroys diseased tissue but leaves healthy tissue in its place; (3) that it leaves small scars; (4) that it can be used when the surrounding healthy tissue cannot be sacrificed (in operations about the eye and nose); (5) that it is applicable in inoperable cases; and (6) that it often relieves pain. With commendable caution he does not advise the use of the x rays for operable malignant growths except for "cutaneous carcinoma" (rodent ulcer). On the other hand, he thinks that the x rays should be used as a prophylactic measure in all cases of malignant disease which have been operated upon and should be tried in all inoperable cases—in which there are a probability of relieving pain and a possibility of inhibiting growth.

THE MEDICAL ORGANISATIONS OF FOREIGN ARMIES.

WE desire to call attention to a very useful little official handbook dealing with the medical organisations of foreign armies (chiefly for war) which has been compiled by Lieutenant-Colonel Frank Howard, Army Medical Staff (retired pay), and is issued by authority. A brief description is given of the army medical organisation of some 20 foreign countries. The information, which must have cost the writer much care and labour to get together, strikes us as being clearly and succinctly epitomised, and, setting aside any intrinsic interest attaching to the subject, the manual supplies a want on the part of army surgeons who will be required to show some knowledge of it in their future examinations for promotion. Readers of the handbook will naturally turn first of all to the medical organisations of the armies of Germany, France, America, Russia, Austria-Hungary, and Italy. Speaking generally, there is a great similarity, on the whole, in the army medical organisation, arrangements, and transport of the different military powers; they all recognise very much the same aims and principles, although there are, as might be confidently expected, some diversities of procedure—of ways and means and details—in carrying them out. The handbook is a little mine of compressed information which does not easily lend itself to review, but we may say that the sections devoted to France, Germany, America, and Japan seem to be full and precise. We should add that the price of the handbook is 1s.

THE LATE MR. BRAXTON HICKS.

WE regret to see the announcement of the death from pneumonia on Saturday last of Mr. Athelstan Braxton Hicks, coroner for the South-western District of London and for the Kingston Division of Surrey. Mr. Hicks, who was a legal coroner, was a son of the late Dr. Braxton Hicks, the distinguished obstetrician, and was, we believe, at one time intended for the medical profession and studied for some years at Guy's Hospital. He eventually, however, was called to the Bar and in 1883 was appointed deputy coroner for Mid-Surrey and subsequently deputy-coroner for the City of London, the Borough of Southwark, the City of Westminster, and Western Middlesex. In 1885 he became coroner for Surrey in succession to the late Mr. George Hull. On the passing of the Local Government Act and the formation of the administrative county of London his district was divided and he became coroner for South-west London and the Kingston division of Surrey. Mr. Braxton Hicks was at the time of his death Vice-president of the Coroners' Society; he also was, and had been for many years, secretary of the society and had a wide knowledge of the laws appertaining to the duties and position of coroners. We have frequently been indebted to him for information of this nature which was always freely and promptly placed at our disposal. As a coroner he performed good public service in many ways. He was largely responsible for the licensing of small boats and did much to bring about an alteration in the law with regard to the sale of carbolic acid. He also missed no opportunity of exposing the evils of baby-farming, and up to the time of his death was engaged in impressing upon the poorer classes of the public the necessity of the provision of fire-guards to protect their children from accidental burning.

A CASE OF ABNORMALLY HIGH BRAIN-WEIGHT.

AN interesting case of abnormally high brain-weight in a man who died at the age of 37 years in an asylum, but who, until the age of about 35 years, had his mental faculties practically normal, is published in the *Journal of Mental Science* for April last by Mr. John Sutcliffe and Professor Sheridan Delépine. The brain belonged to a man who was by profession an accountant and estate agent, a sober, steady, hard-working man, who had built up a good business. He had married at the age of 21 years and was the father of four children. He had had good health till the age of 22 years, when epileptic fits began to appear, one fit occurring at intervals of two or three weeks. When 25 years old he was assaulted and knocked down and remained unconscious for three days. Since then the fits became severe and frequent and he also suffered from headaches. For some months before admission to the asylum at Cheadle—viz., Feb. 6th, 1900—he had been suffering from delusions of poisoning and from excitement. The symptoms on admission were those of epileptic insanity but they passed away while under treatment and he was discharged as recovered. His malady recurred in January, 1901, and he was readmitted to the asylum. His condition was then grave, he had frequent epileptic attacks, his delusions were re-established, and there was optic neuritis. He died in a state of coma on July 22nd. Post-mortem examination showed that the brain was enlarged generally, and that the cerebral convolutions were flatter and broader than normal. The entire brain (cerebrum, cerebellum, and pons) weighed 69 ounces. The naked eye distinction between grey and white matter seemed to be obliterated in sections of the convolutions and microscopical examination showed diffuse hyperplasia of the neuroglia elements throughout the brain, the overgrowth giving rise here and there to masses of soft neuroglia. The case was one of so-called diffuse "hypertrophy of the brain"—really a hypergliosis—which accounted for the abnormal increase of weight. The heaviest normal brains hitherto recorded were those of Cuvier the naturalist, which was 64½ ounces, and of Abercrombie the physician, which weighed 63 ounces.

---

[1] THE LANCET, May 17th, 1902, p. 1395.

THE DISTRIBUTION OF PLAGUE.

IN Cape Colony during the week ending April 26th, 11 cases remained under observation, all Europeans, 6 of whom were males and 5 were females. The distribution of plague throughout Egypt during the week ending May 11th was as follows: 1 case and 1 death at Alexandria, 4 cases and 2 deaths at Deshneh, 1 case and 2 deaths at Tala, 3 cases and 1 death at Maghagha, 10 cases and 2 deaths at Toukh, 1 case and 1 death at Shebin El Koum, 1 case and 1 death at Ashmoun, 7 cases and 2 deaths at Samalout, and 1 case at Menouf, making a total of 29 cases and 12 deaths. Cases have been reported from Kolosneh in the Markaz of Samalout, and at Minieh Moudirieh, which is not very far from Maghagha; 1 case was notified at Shebin El Koum and other cases at Syaffa, Tant El Gheziroh, Bir El Shems, and Kafr El Faranieh. All these are small villages situated close to others in the Moudiriehs of Galioubieh and Menoufieh. Our Brazilian correspondent, writing from Recife, Pernambuco, during April, says that the bubonic plague has broken out in Recife. He continues: "Plague was first imported into South America in 1899, when it appeared in the slums of Rio Janeiro. The present is its first appearance in the State of Pernambuco and it is supposed to have been imported by a Spaniard who travelled by train from Santos. This man's illness was notified as plague to the Public Health Committee on March 28th by Dr. Simões Barbosa. The patient was 24 years of age and died five days after the onset of the febrile symptoms. He had a bubo in the left groin and another in the right axilla. A microscopical examination of his blood was made by the Government pathologist and the Kitasato cocco-bacillus was found in it. The pus of both buboes was examined with negative results but some of the pus injected into a rabbit gave rise to all the symptoms of plague and killed the animal on the fourth day. Up to the present date 48 cases of plague have been reported and 29 deaths have occurred. The port is in quarantine by sea and land and everyone who wishes to leave Recife by ship or by train is obliged to undergo disinfection. The disinfection is thus carried out. The person lies for a quarter of an hour in a bath of formol solution, then he is washed down with a lather of corrosive sublimate soap, and afterwards dried. His clothes are put into an *étuve* and cleansed by dry heat. At first when the pest declared itself there was no place in which the sick might be looked after and properly isolated. They were left in their own houses, which were guarded by soldiers, and were visited only by the public health officials. The populace was in a state of panic just then and trained nurses could not be obtained. Nearly every one of the first 20 cases died. Later an isolation hospital was opened at Pina on a small island a mile distant from the town of Recife. Patients are now taken there in a specially appointed boat. On their arrival they are well nursed and cared for and a microscopical examination of blood and dejecta is undertaken in every case. One type of case has hitherto predominated and its course is as follows. After an incubation period of only two days there sets in a prodromal stage of malaise, rigors, vertigo, and dull aching at the seat of the future bubo. After two or three hours the first stage begins, with rise of temperature, staggering, prostration, intense thirst, and loss of voice. The face is haggard and terrified looking and the eyes are bloodshot, staring, and sunken. There are vomiting and much diarrhœa. Death occurs with a gradual weakening of the action of the heart and is preceded by much cyanosis. Hæmorrhages of all kinds are frequent. The fever lasts for about a week in favourable cases and defervescence is by lysis. In this epidemic all the patients who lived more than four or five days developed buboes. The swellings were generally in the glands of the femoral triangle and discharged pus and débris when incised. The resulting wounds, especially when septic and occurring in asthenic patients, took a long time to heal and formed large indolent ulcers. The treatment adopted here has been, and is still, mainly symptomatic. The chief antipyretic measure employed is cold sponging; morphine is given for sleeplessness and strychnine is given throughout. The buboes are incised early and are dealt with on ordinary surgical principles. There are several advertisements in the local papers inserted by medical men referring to the prophylactic inoculation for plague as practised by Haffkine. So far as I have been able to learn Yersin's serum, which was so successful in China and so useless in India, has not been tried in Recife. It seems that the plague is already slowly diminishing, but some of the conditions of life under which it started are much as they were before in spite of the efforts of an enlightened Public Health Committee. Just before the outbreak there had been a spell of extremely hot dry weather and the general health of the public was of a low standard. The soil and streets were abundantly saturated with animal and vegetable refuse; there were crowds of vermin, flies and mosquitoes, and rats and mice. The houses of the poor are ill-drained, ill lighted, and ill-ventilated. The people are careless, idle, ill washed, ill-fed, and ill-clothed. Their thoroughfares are narrow, unwatered, and stink of accumulated garbage. Dead rats, mice, and lice lie about the place. Quite recently the bishop spoke of this state of things from the pulpit and referred to the plague as a visitation of God. I beg to acknowledge my indebtedness to Dr. Alves Pontual of this town for most of the details here set down." For the week ending May 17th 31 cases of bubonic plague and 34 deaths have been notified at Hong Kong.

A CHILDREN'S AMBULANCE SERVICE.

THE crippled children of the poorer classes are in several respects entitled to our sympathy, for their prospects in life are not of the brightest. Not only does their physical infirmity restrict their choice of an occupation but it has the further disadvantage that during early life it seriously interferes with their attendance at school or may even render it almost impossible for them. In London, however, this difficulty has been surmounted by the thoughtful care of the School Board which has provided a service of well-equipped vehicles for the conveyance of these helpless ones to and fro between their homes and the schools. The word "ambulance" may perhaps at first sight seem to be not altogether appropriate in this connexion, but the designation is nevertheless quite correct, for the vehicles are fitted up with special invalid couches and have removeable stretchers on which pupils may, if required, be conveyed undisturbed from their own apartments to their places in the class-rooms. The vehicles are constructed to carry seven or eight children, together with the nurse in charge. They have a neat appearance, resembling that of a small omnibus.

ARTHUR MARTIN-LEAKE, V.C.

WE announced last week that His Majesty the King had awarded the much-coveted decoration for valour, the Victoria Cross, to Surgeon-Captain Arthur Martin-Leake, of the South African Constabulary. Surgeon-Captain Martin-Leake is one of the four sons of a well-known barrister, the late Stephen Martin-Leake, author of an excellent legal text-book. After leaving Westminster School he received his medical education at University College Hospital, the choice of hospital being dictated by the fact that his uncle by marriage, the late Sir John Russell Reynolds, who had a great regard for him, was consulting physician to the institution. When the news of the early disasters attending the South African campaign reached England Arthur Martin-Leake, who had served his time as house surgeon at University College Hospital, volunteered for service as a civil surgeon. The War Office, however, stated that no more surgeons were required for the forces—at that time such was the stereotyped answer given to medical men who offered help. He therefore went out as a trooper in the Herts Yeomanry. After a year's service he was given a civil post on the medical staff at Pretoria and again about a year later was appointed to the South African Constabulary, in which service he has literally covered himself with glory. Mrs. Martin-Leake, his mother, may well be proud of her family, for the wearer of the Victoria Cross is one of four sons who are actively serving the Empire. One is a captain in the Cheshire Regiment now serving in South Africa; another is in the Royal Engineers, and was in Peking during the *émeute;* and a third is in command of H.M.S. *Bramble* now in Chinese waters. We congratulate Surgeon-Captain Martin-Leake upon his splendidly earned distinction.

GAS AS A SOURCE OF POWER.

APROPOS of Sir J. Crichton Browne's vigorous denunciation of the smoke nuisance at the recent Sanitary Conference at Manchester an important resolution was passed at the last meeting of the City Council of that town reducing the price of gas for power purposes from 2*s.* 9*d.* to 2*s.* per 1000 cubic feet within the city and from 3*s.* to 2*s.* 3*d.* without the city, separate fittings being provided by the consumer. The reason given is the dread of the competition of Mond gas. It was stated by one of the members that the latter "could be produced at a tenth of a penny per horse-power per hour," and he thought that the corporation would do well to reduce the price for power to 1*s.* 6*d.* or even 1*s.* per 1000. Another speaker thought that the smoke pollution was caused mostly by cottages and that the encouragement of the use of "gas cookers" would tend more than anything to reduce the smoke nuisance. The small manufacturers who try "to get more power out of their machinery than their boiler-room would afford" were considered to be greater offenders than the larger ones, but when the great chimneys are pouring out their inky clouds we are reminded of the kettle calling the pot black. However the production of smoke is apportioned among these various agencies the total results are disastrous to the amenities of town life and depressing to the health and vigour of many hundreds of thousands in Manchester and Salford. But habit brings indifference, and it would astonish many to hear Sir J. Crichton Browne saying to them, "You are smothered in the products of combustion all the year round; in winter these settle down on you in fogs, grim and horrible. ...... A sable incubus embarrasses your breathing, a hideous scum settles on your skin and clothes, a swart awning offends your vision, a sullen cloud oppresses your spirits, and you quietly tolerate all this, apparently having come to regard it as inevitable and as a penalty inseparable from industrial prosperity"; and he then went on to show that this curse of the towns might be mitigated, if not entirely removed. It would be worth while to make little or no profit from gas if by its use the manifold injuries caused by smoke could be prevented.

DEATH IN THE POLICE CELL.

AN inquiry was held recently at Streatham concerning the death of a medical man in a cell at the police-station in which he had been placed because he had been found lying helpless in the public highway, so that the police were under the erroneous impression that he was drunk and incapable, and in which he died without medical assistance being summoned. The danger to members of the community owing to the confidence thus placed in the unaided diagnosis of the constable or the police-serjeant is frequently brought before our notice and we should have thought that by this time it would have obtruded itself upon the observation of the higher authorities responsible for the regulation of the police force. We concede that a large number of the persons brought into our police cells as drunk and incapable from the streets are in fact drunk and incapable and suffer no particular harm from being left in a recumbent position to "sleep it off" on a plank bed. We concede that in the case to which we are calling attention there may have been little in the symptoms readily observable to distinguish the case from drunkenness. We would, however, ask the consideration of the police authorities for certain propositions which seem to us pertinent, not only to the case of the medical man which we are dealing with quite apart from his connexion with the medical profession, but to a very large number of cases of illness and accident. Respectably dressed persons do not as a rule allow themselves to be overcome with drink in public places to the extent of having to lie down in the street without power to get themselves conveyed to their homes. Respectably dressed persons have usually documentary evidence of their identity about them and their friends can be communicated with. Nearly all persons picked up in the streets smell of drink because some are drunk, some on feeling ill have dosed themselves with spirits, and others have been in the hands of Samaritans whose first idea has been to pour alcohol down their throats, perhaps spilling a considerable quantity on their clothes. Many, if not most, of the class likely to be under the influence of drink are known to the police in the district in which they live. The man known to frequent a certain public-house and to get drunk there, if he is picked up insensible outside it, cannot complain if the policeman who takes him to the station forms an opinion as to the cause of his condition. But even in his case there is something to be said on the side of caution. Even the person who is under the influence of drink and drink only, or of a temporary seizure for which drink alone is responsible, should not be left to pay the penalty of his folly with his life, if his life is in danger. The person to decide the question whether there is such danger is the divisional surgeon and not the policeman, and the policeman should summon the surgeon, at any rate in all cases of insensibility. It is better that this should be done on some occasions unnecessarily than that life and Civil Surgeons Summerhayes, Cavanagh, and Hogg are on passage home.

ARMY MEDICAL SCHOOL, NETLEY.

The eighty-fourth session of the Army Medical School was opened on April 1st. The classes are attended by 37 surgeons-on-probation for His Majesty's Indian Medical Service. 33 of these gentlemen have entered the school by competing at the examination recently held, and four of them by the nomination of the Secretary of State for India. The nominees are medical men who have served on plague duty in India. The following is a list of these gentlemen:—

F. A. F. Barnardo.
J. McPherson.
W. O. Ross.
J. O. G. Kunahardt.
G. D. Franklin.
J. H. Gill.
R. A. Lloyd.
C. A. Gourlay.
E. A Walker.
F. Sime.
L. L. Hirsch.
H. Ross.
H. E. J. Batty.
G. J. Davys.
A. J. V. Betts.
H. Halliday.
F. E. Wilson.
B. B. Paymaster.
H. Crossle.
L. Cook.
J. Forrest.
L. B. Scott.
J. H. Ferris.
W. S. Patton
N. W. Mackworth.
W. L. Trafford.
L. Rundall.
E. C. C. Maunsell.
G. C. J. Robertson.
D. S. A. O'Keefe.
J. W. Illius.
W. C B. Smith.
J. P. Cameron.
H. Gloster.
J. H. Horton.
W. A. Justice.
H. H. G. Knapp.

THE LOSS OF THE SLOOP "CONDOR."

The loss of the sloop *Condor* and her crew having now been officially recognised, we regret to record the death of Surgeon T. S. Hartley, R.N., M.R.C.S., L.R.C.P. Lond., who was medical officer on board that ill-fated vessel.

QUEEN ALEXANDRA'S IMPERIAL NURSING SERVICE.

A Royal Warrant has been issued providing for the establishment of an Imperial Military Nursing Service to be designated "Queen Alexandra's Imperial Nursing Service," and notifying the amendments in the Regulations contained in the Royal Warrant of the late Queen, dated Oct. 26th, 1900. It has been framed, as anticipated, very much on the lines with which our readers are already acquainted.[1]

Correspondence.

"Audi alteram partem."

THE PROSPECTS OF THE GENERAL HOSPITALS OF LONDON IN THE PRESENT CENTURY.

To the Editors of THE LANCET.

SIRS,—There is no doubt that before many years of this twentieth century are past the very serious question of adequate hospital accommodation for the poor of London will be forced once more upon the public During the last 50 years vast changes have been taking place in the residential quarters of the poor, and now, on the eve of improved methods and greater facilities for the rapid transmission of the public between the centre and various points on the circumference of the great city, even greater changes must follow, for it is becoming obvious that the whole of central London must be given up to the requirements of professions and trades and there will soon be no space in this region for the residences of the poor. It may be as well if I define what is meant by the term "the poor." Firstly, there is the very large group of those who have no regular employment and who pick up a livelihood by odd jobs, both honest and dishonest. The greater number of these were herded together until recently in three or four "slum neighbourhoods" in the West Central district. One such area existed on the site of the present law courts; another (Clare Market) is now being demolished; another, round Endell-street, has almost ceased to exist; and the same may be said of that one which exists on each side of Theobalds road. These people have migrated chiefly to the north of King's Cross and to the Surrey side of the river, many having gone as far as Islington and Holloway. Secondly, there is a group of those who are out of work for the time being; they are the most difficult from the hospital point of view, for when in work they are often well able to pay a medical man and when out of work are practically destitute, for they never save money when they are in regular employment. It is these people who often abuse the hospitals most, for they come first when nearly destitute and go on attending when they could well afford to pay a medical man. Thirdly, there is the class of people who can afford private medical and surgical advice for small things, but are, nevertheless, proper cases for hospitals when they have any serious or long illness. This class often includes many people who are obliged to appear decently dressed and have to expend money on travelling to and from their work.

While, therefore, the poor have been steadily forced, and will be still more forced, from these central parts our great general hospitals have, without exception, remained where they were. The almost certain result must be that in a few years the poor who seek relief as in- or out-patients will have to travel from the circumference to the centre of the city before they can obtain it. It may be said that just as the facilities for cheap and rapid travelling become extended, so the journeys of the sick poor to the great hospitals will at the same time be shortened; but is this by any means a desirable state of affairs? Should not the sick poor be able to obtain relief near where they are living? I think there are few, whether they be committee men or professional men, belonging to the great general hospitals who would not admit that those seeking medical or surgical help ought, on all grounds, to be able to obtain it close at hand. Such being the case, there are only two alternatives: (1) to transfer our great general hospitals further away from the central regions of London; or (2) to build new general hospitals at the circumference. In the former case of course provision would have to be made for "emergency cases" occurring in the central regions of London by the erection of suitable receiving rooms and wards. There is also a possibility that some of the larger hospitals might join with some of the smaller general hospitals which now exist on the circumference of the great city—four or five miles from Charing Cross-road.

It may be urged that in the case of some of those hospitals within one and a half miles of Cambridge-circus the wards are kept well filled and the number of out-patients is still large, but what are the proportions of the patients coming from the immediate neighbourhood of these hospitals to those coming from a distance, and, in many cases, sent up from the country and elsewhere in order that they may be under the care of certain members of the staff? I may safely assert that in the case of more than one of these hospitals the material for teaching would be quite inadequate were it not supplemented by cases coming in, or sent up from a distance. Moreover, how many in-patients are there—mentioning surgical tuberculous cases alone—who are ofte kept in the wards for weeks because it is not possible t obtain sufficient orders for convalescent homes for them. How much better off would such cases be were they treated in a hospital in the outskirts, rather than in the centre of London.

From the point of view of relieving the sick poor the ideal plan would be to demolish many of the large hospitals now in the central districts of London and to rebuild them in the outlying districts to which the poor are now rapidly migrating. In many cases the money obtained from the sale of the extremely valuable land upon which these hospitals now stand would be nearly sufficient to pay for their erection elsewhere; then each hospital would be obliged to erect a small and compact casualty and out-patient department, together with wards for, say, 100 beds, close to its old site. Here urgent cases would be dealt with until fit for removal to the outlying hospital. This would entail the provision of horsed or motor ambulances such as are at present in use by the hospitals of the Metropolitan Asylums Board. When we consider how smoothly that system of conveying fever cases between their homes and the hospitals now works, and how extensively it is adopted, there can be no objection raised to its adoption in the case of other institutions. At the Pendlebury Children's Hospital, near Manchester, the receiving room is in Manchester itself, and this system has been at work for some years.

This brings me to the subject of Poor-law infirmaries. These institutions are acting now, to some extent, merely as receiving places for cases which the hospitals are unable to keep, owing to the continual pressure of serious cases upon should be sacrificed in the case of persons whose misfortune it has been to be taken ill in a public place and alone; while in the case of the drunkard a fine at the police-court in the morning, and not death in the cell over night, is the punishment which his transgression of public decency justifies.

---

[1] Vide THE LANCET, Oct. 12th, 1901, p 996.

THE PREVALENCE OF SMALL-POX.

THE number of cases admitted to the institutions of the Metropolitan Asylums Board since Friday, May 16th, is as follows:—On Saturday, the 17th, 32 cases; on Sunday, the 18th, 22 cases; on Monday, the 19th, 57 cases; on Tuesday, the 20th, 54 cases; and on Wednesday, the 21st, 36 cases. The bi-monthly report issued by the Local Government Board of Scotland shows that the number of cases of small-pox notified during the period May 1st to 15th inclusive in the following counties was Forfarshire 1, Lanarkshire 18, Renfrewshire 2, and Roxburghshire 1, making a total of 22. In the county of Essex the number of cases of small-pox notified for the week ending May 17th was 32.

SENSATIONAL EXHIBITIONS.

THE papers have recorded this week the death of another victim of the craze for sensational exhibitions. At Owlerton, Sheffield, on May 20th, an unfortunate girl was killed when attempting a descent with a parachute, the parachute having failed to open when she jumped from the balloon which had attained a considerable altitude. Exactly similar accidents have happened before and probably exactly similar accidents will happen again. The victim's sister nearly came to grief on the previous day when the balloon was damaged, and yet another accident was narrowly averted at Bradford recently when a parachute came into contact with a church spire. We understand that there were several thousands of spectators of the incident at Sheffield, and they may, without much exaggeration, look upon themselves as accessories in a case of suicide. If a life were not at stake there would be no excitement about such exhibitions. No particular skill is required to make a descent with a parachute. If the parachute opens properly the performer drops gracefully to earth; if anything prevents it from opening the performer is smashed to pieces. Apparently the attraction to the sight-seer lies in the fact that he may witness a tragedy. It seems to us that the sooner such displays are rendered illegal the better it will be for the moral welfare of the community.

THE LOSSES OF WAR.

THE *Standard* of May 20th contains an interesting communication from its Odessa correspondent in which a comparison, based upon official returns and upon recent articles in the Russian military press, is instituted between the British losses from disease and wounds in the present war in South Africa and those suffered by the Russians in the course of their last Turkish war. In that war, which was of some 18 months' duration, whereas the Boer war covers a period of 30 months or about a year in excess of the Russo-Turkish war of 1877-78, the Russian forces of all arms numbered altogether 505,000 (twice as many as the British troops in South Africa). The Russian army was divided into two great wings, the right covering the Danube and the left striking from the Caucasus. The army of the Danube lost 51,000 men through disease and 16,000 from wounds, while of the army of the Caucasus 37,000 died from disease and 12,000 succumbed from wounds. The total loss was accordingly 88,000 from disease and 28,000 from wounds, or 116,000 altogether. The most severe losses, amounting in all to 31,000, on any single battle-ground were naturally those sustained before Plevna in the three Russian assaults on that garrison stronghold. The results of the comparison, so far as they go and so far as any comparison can be instituted between the Russo-Turkish campaign and that in South Africa, are, as will be seen, highly favourable to the British mortality returns of the present war.

PATRONYMICS OF MEDICAL LONDON.

A CORRESPONDENT has been making investigations with regard to the numbers of surnames having the same initial and included in the "London" section of the Medical Directory for 1902. He finds that the most frequent initials stand in the following order: B, 701; S, 587; M, 568; H, 514; C, 503; and W, 481 names. These initials thus account for 3354 names out of the 6292 names stated by the publishers of the Directory to be in the "London" list, so that one out of every two medical persons in London bears a family name with one of the above six initials. The most infrequent initials are: V, with 46 names; Y, with 25; I, with 19; U, with nine; Q, with five; and Z, with two, while X does not occur. It may be mentioned for purposes of comparison that for the "Provincial" list the sequence of initials is almost the same, while for "Scotland" and "Ireland" the predominating initial is M and for "Wales and Monmouth" it is J.

A MEDICAL HISTORY OF THE OPERATIONS IN CHINA, 1900-1901, BY THE PRINCIPAL MEDICAL OFFICER OF THE FRENCH EXPEDITIONARY FORCE.

THE whole of the *Archives de Médecine Navale* for March is devoted, with the exception of some half-dozen pages, to the first part of a medical report on the recent operations in Northern China by Dr. Jacquemin, principal medical officer of the French troops, with the collaboration of his staff officer, Dr. Bourns. It is an outspoken document and promises to be of considerable value not only as a faithful record of events but also for future guidance, should similar cases occur. It was not till July 20th, 1900, that the author received his orders to prepare the medical portion of the expedition. On August 10th he embarked at Marseilles, the intervening period of exactly three weeks having been spent in procuring an outfit almost *ab initio*, so unprepared was the medical department of the French navy for the demands thus suddenly made upon its resources. For his complex and indispensable *matériel* Dr. Jacquemin had to seek in various directions. The War Department lent him hospital requirements—furniture, beds, ambulances. From the Ministry of the Navy he procured drugs, dressing material, comforts, and clothing. Finally, he had to purchase in the open market such articles as filters, water-sterilisers, disinfecting machines, and all the appliances required for radiography and bacteriology. The report is divided into four parts under the following headings: (1) Organisation and Procedure of the Health Service; (2) the *Matériel* of the Service; (3) Medical Notes on the Foreign Armies in China; and (4) Statistics and Medical Matters. As far as it is possible to judge from the present instalment of his report Dr. Jacquemin seems to have met with unusual facilities in the execution of his important duties. "We were able," he says, "from the moment of our arrival to install at Tien Tsin, and also at Pekin, hospitals of 250 beds which had no cause to envy similar establishments at home." Elsewhere also he observes: "The General Commanding in Chief at one of his earliest conferences with heads of departments said, 'The health service should come before everything else. It is my desire that all the other services shall do their utmost to facilitate its task.' We are bound," continues Dr. Jacquemin, "to acknowledge with gratitude that these orders were carried out not only with exactitude but also with goodwill and rapidity. Staff officers refused us none of the sacrifices which we required of them—necessary credits, choice of quarters, *personnel.*"

A LETTER written on behalf of the council of the Sanitary Institute was published in the *Times* of May 17th inviting attention to the urgent necessity which exists for enlarging the premises of the Parkes Museum. It is estimated that a sum of £25,000 will be required for this purpose, towards which about £8000 have already been raised. The museum has now become a practical demonstration school for illustrating and teaching all matters relating to sanitation and hygiene and the available space is hardly sufficient for the increasing work that is being carried on. The museum receives no grant from any public funds and is maintained by the Sanitary Institute at a considerable annual cost. THE Duke of Northumberland, Vice-President, will preside at the Sanitary Institute Coronation Dinner to be held on Monday, June 2nd, at the Midland Grand Hotel. All communications should be addressed to Mr E. White Wallis, F.S.S., secretary of the institute.

THE general meeting of the British Balneological and Climatological Society will be held on Tuesday, June 3rd, at 20, Hanover-square, W., at 5 P.M. At 6.30 P.M. on the same day the annual dinner will take place at Pagani's Restaurant, Great Portland-street, W., and at 9 P.M. a conversazione will be held at 20, Hanover-square, W., when Sir Lauder Brunton, M.D., F.R.C.P., will deliver an address. Communications should be addressed to the honorary secretaries, Dr. Septimus P. Sutherland, 11, Cavendish-place, W., and Mr. H. Shirley Jones, Droitwich, who are inquiring for articles relating to balneology and climatology to exhibit at the conversazione.

THE anniversary dinner of the members of the Imperial Yeomanry Field Hospital and Bearer Company in commemoration of their capture at Roodeval will be held at the Criterion Restaurant on June 7th. Members wishing to attend who may not already have received notice are requested to communicate with the secretary, Mr. Oliver Williams, 116, Victoria-street, Westminster, S.W.

A DINNER of the Ophthalmological Society of the United Kingdom will be held on Friday, June 13th, at the Trocadero Restaurant at 7.30 P.M., Dr. Little, the President, in the chair. All communications should be addressed to Mr. Hall at 11, Chandos-street, W. The Bowman Lecture will be delivered on the same day by Professor Fuchs of Vienna, at 4.30 P.M.

A DISTRIBUTION of prizes gained by successful students at the Charing Cross Hospital Medical School will be made by Sir Frederick Treves, K.C.V.O., C.B., F.R.C.S., on Wednesday, June 11th, next, at 3.30 P.M.

THE Registrar announces that the next session of the General Council of Medical Education and Registration will begin on Tuesday, May 27th, at 2 o'clock P.M.

WE are informed that a rumour of the death of Professor Groedel of Bad-Nauheim which is stated to have obtained some currency is happily untrue.

OBSERVATIONS ON DIET.

BY HARRY CAMPBELL, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE NORTH-WEST LONDON HOSPITAL; PHYSICIAN TO THE WEST-END HOSPITAL FOR NERVOUS DISEASES, WELBECK-STREET, W.

I.—QUANTITY OF FOOD.

THE question how much food it is advisable for an individual to consume is one of vast importance to the physician. He may sometimes save a life by entirely withholding food for a time; very often he may do great good by curtailing the diet of a habitual over-eater; in other cases, again, the opposite plan of gorging the patient may effect a cure.

At the outset it has to be decided what constitutes the normal allowance of food. Obviously no cast-iron rule, applicable to each and every individual, is available here. The decision will depend upon a variety of circumstances now to be considered. In my remarks on this head I shall assume that the various nutritive ingredients—proteids, fats, and saccharides—are correctly proportioned.

Circumstances influencing the Amount of Food required.

The quantity of food required is largely regulated by the rate of katabolism: the more rapid that this is the larger is the amount of food needed. The rate of katabolism varies with many circumstances, such as age, sex, idiosyncrasy, size, external temperature, and the amount of exercise taken; consequently these become determining factors.

Age.—The period of growth is characterised by great katabolic activity and a correspondingly large supply of food is demanded during it. This active katabolism is due partly to the fact (to be referred to later) that small animals katabolise, if I may be allowed the expression, more rapidly than large ones and partly to the abounding activity of the muscular system which prevails in early life, but chiefly to the rapid formation of new tissue. Why this latter necessitates very active katabolism cannot be explained. That it does so is evident: the large supply of food required by the constructive process is vastly in excess of the amount which is converted into, and retained as, new tissue. Evidently the construction of animal bioplasm involves a lavish expenditure of building material; for consider how small is the daily increase in weight as compared with the amount of food taken: the average yearly increase of weight from birth to the age of 20 years is about half a stone or less than a third of an ounce each day—a quantity represented by a moderate mouthful of food—and this quantity is so insignificant in comparison with the total amount taken daily as to be practically negligible. The abundance of food required by the rapidly-growing individual, say at puberty, is therefore to be explained by the activity of katabolism then prevailing, and not by the quantity actually laid down as new tissue.

The rate of katabolism and therefore the amount of food required remain much the same from the beginning of maturity till the age of 40 years or thereabouts, when they diminish in progressive ratio till the end of life; slowly from 40 to 50 years, more rapidly from 50 to 60 years, and still more rapidly from 60 to 70 years, until, when extreme old age is reached, katabolism has become so sluggish that a surprisingly small quantity of food is needed. That "old people bear abstinence well" is an observation dating from Hippocrates. To make the aphorism complete it should be added that they "bear excessive eating ill." This is one of the most important therapeutic truths that I know.

Sex.—The male Human needs more food than the female, not only on account of his larger stature but also because he is the more katabolic of the two. The man tends to expend energy and the woman to store it up in the form of fat: he burns the faster. This sexual difference shows itself in the very blood; the man has a larger percentage of chromocytes than the woman, showing that he needs a proportionately larger quantity of oxygen in order to maintain his more active combustion—a fact which one may associate with his comparative freedom from chlorosis; moreover, weight for weight, his pulmonary capacity is greater than that of the woman whose smaller respiratory need is further shown by the facility with which she can without discomfort diminish her breathing power by means of the corset. The great contrast between the metabolic activity of the two sexes was forcibly brought home to me by a military display given by a troupe of dusky amazons, with whom were also a few male warriors. The women, in spite of their daily exertions, were all rounded and plump, some very much so, no single muscle showing through the skin, and it was noticed that their movements, though full of grace, lacked energy and "go." The men, on the other hand, were spare, their muscles standing out plainly under the shiny skin, and they, in further contrast with the women, displayed a truly amazing agility, bounding about and whirling round in a most astounding fashion: the women, in short, were essentially anabolic and the men were katabolic. I may here draw attention to the fact that men are apt to be larger meat-eaters than women, just as they are, possibly in consequence of this very fact, more prone to drink alcohol and to smoke tobacco.

Idiosyncrasy.—Some individuals are so constituted as to require more food than others. This may partly be explained by peculiarities of digestion, some digesting and absorbing their food more completely than others and consequently requiring so much the less of it; but it is, I doubt not, chiefly referable to differences in katabolic activity. Some burn off the absorbed food more rapidly than others. Compare the thin, wiry, restless, energetic individual with his fat, phlegmatic brother. The one no amount of gorging will fatten and the other a starvation diet will scarcely make thin; in the one the metabolic clockwork is regulated to go fast, so to say, and in the other to go slow. As exaggerated examples of these two types take the subject of Graves's disease and of myxœdema. The heightened katabolism in the former case is due to an excess of (perverted?) thyroid secretion in the blood, just as the depressed katabolism in the latter disease is due to a deficiency of this secretion. Thyroid secretion, in fact, plays the part of a bellows, causing the vital fire to burn more fiercely and increasing the output of urea, carbonic acid, &c. One can scarcely doubt, in short, that the differences of katabolic activity among normal individuals depend to a large extent upon the activity of the thyroid gland; and we may be sure that there are many kindred influences affecting the rate of katabolism of which we are as yet ignorant.

Size.—Obviously the quantity of food required is largely influenced by the size of the individual. Those of large stature need more than those of small stature; per unit of body-weight, however, they require less, because in man, as in all other warm-blooded animals, metabolic activity tends to vary in inverse ratio to body-weight, for the smaller the animal the larger is its surface in proportion to weight and the greater, therefore, are the proportional loss of heat and the need for food to supply that loss: the mouse requires much more food in proportion to its weight than does the elephant.

External temperature.—The colder the weather the greater is the loss of heat and the more active is the katabolism in order to make good the loss and the greater is the demand for food in consequence. The Esquimaux are said to consume prodigious quantities of food, notably fat. By means of warm clothing man is able to lessen the loss of heat in cold weather and the more effectually that he does this the less will he need to increase his diet. In warm weather, on the other hand, katabolism tends to be depressed owing to the comparatively small loss of heat, and there is a correspondingly small need of food for the generation of heat. Possibly a bracing climate, apart from the influence of temperature, tends to stimulate metabolism; at all events it tends to increase the appetite. An open-air life has the same effect quite apart from the fact that it generally goes along with muscular activity. It is not easy to explain why this is so; possibly more oxygen is absorbed in the open air than indoors and it is probable that the mere impact of moving air against exposed parts excites katabolism by stimulating the cutaneous nerves and by augmenting the loss of heat. Certain it is that rapid motion through the air increases the appetite and in this connexion one recalls the fact that a horse travels better on a hot day against the wind than with it.

Muscle exercise.—Among the influences which determine the rate of katabolism, and therefore the quantity of food required, the degree to which the muscular system is exercised occupies a prominent place. When a person is kept quiet in bed he needs comparatively little food but when his muscles are doing laborious work, as in the case of a soldier on a forced march, he requires a large amount—as much, indeed, as his digestive organs can cope with,—so that it is difficult, if not impossible, for those regularly engaged in laborious work habitually to over-eat, as witness the rarity of obesity among them. The moral to be deduced from this is not only that those who exercise the muscles much need large quantities of food but also that those who eat liberally should take abundant exercise; and often the chief reason for insisting on exercise being taken is that the evils of an excessive diet may be counteracted. Those who lead sedentary lives should be constantly on their guard against excesses at the table. On the other hand, the evil effects of a sedentary life may be reduced to a minimum by a spare diet. Accounts are constantly read in the papers of some recluse who, after living for years in one room, finally dies at an advanced age; and in all such cases it will be found that the diet has been spare, oftentimes on account of a miserly disposition. Those, and they are many, who are compelled to lead a sedentary life may take comfort from this fact. It is the high living with little exercise that does the harm, not so much the little exercise itself, and it need scarcely be said that these remarks apply especially to middle and late life; not only is youth the period *par excellence* of muscular activity but also an excess of food is then most easily dealt with; in middle and late life, on the other hand, there is a growing tendency to sedentariness, while the tissues become less and less capable of coping with a redundancy of food.

CLASSIFICATION OF DIETARIES ACCORDING AS THEY ARE SUFFICIENT, INSUFFICIENT, OR EXCESSIVE.

Food may be sufficient, insufficient, or excessive in quantity. In judging whether a given dietary falls into one or other of these categories the physician cannot, of course, rely solely on the mere weight of the food consumed; for on the one hand, a diet which is considerable as tested by mere weight—such as a purely vegetarian one, for instance—may be deficient in some nutritive ingredient, and, on the other hand, a diet which is small in weight—such as a purely animal one—may be excessive in another; but, as already observed, I shall assume in discussing the subject of the quantity of food that the various nutritive ingredients are correctly balanced.

A Sufficient Diet.

By a "sufficient" diet I mean one just sufficient to maintain the normal body-weight; a diet which falls short of this is "insufficient" and one which goes beyond it is "excessive." It has, then, to be decided what the normal weight is. This cannot be done in the case of the growing individual whose weight is constantly changing, but here instinct affords a sufficiently accurate guide as to the amount of food that should be consumed, always provided—and the qualification is an important one—that it is plain and wholesome. If the food-supply is not sufficient there will be unmistakeable evidence of it in the shape of defective growth and nutrition, and if it is in excess, well, no great harm is likely to follow, except in the case of babies, to which reference will be made in due course. It is chiefly in the case of the adult that it is needful to have a precise test as to what constitutes a sufficient diet. Now the normal weight of an adult I take to be *the minimum weight consistent with the best health of which the individual is capable.* In order to ascertain this the physician, in the case of a stout person, curtails the diet and cautiously diminishes the weight until he is satisfied that any further reduction would be harmful; while, on the other hand, in the case of a thin person who is ailing, he increases the diet and the weight until he believes the highest level of health to be reached. When he has obtained the approximate normal it may be needful still further to reduce or to increase the weight and thus cautiously to feel his way to the actual normal. Some care may be required to get at the right result, as when, for instance, the weight is actually increased by cutting down a diet that has been excessive, an effect which I have more than once seen.

In deciding what is the normal weight due allowances must be made for age, sex, and idiosyncrasy. Middle aged people may be normally somewhat stout, just as the aged normally incline to leanness; young women are naturally stouter than young men; some, again, are by nature thin and others are stout irrespectively of age and sex and so on.

Actual quantity of food constituting a sufficiency.—It is often most useful to determine the actual quantity of food constituting a sufficiency for a given individual—i.e., the smallest quantity on which he can maintain his normal weight—for his health may frequently be greatly improved by raising or reducing, as the case may be, his diet to this level.

Such a bare sufficiency can never be reduced without causing harm and may often, in fact, be temporarily increased with advantage. Dr. R. Hutchison, indeed, argues that it is not advisable to supply the organism with a bare sufficiency and that a certain margin of excess should always be allowed.

While the actual quantity constituting a sufficiency in any given case can only be determined by experiment, it is yet useful to have a rough notion of what it is in different classes of individuals. Among those leading muscularly active lives a sufficient diet varies from three to five pounds per diem. A man doing a moderate amount of muscular work takes on an average about three pounds—i.e., 48 ounces—per diem. For a professional man taking little exercise 30 ounces a day constitute a fair average; this is the amount which Pavy gives as his own daily allowance, thus distributed: eight ounces for breakfast, six for luncheon, and 16 for dinner. The middle diet at Guy's Hospital totals up to 29½ ounces and this for patients who are taking little or no exercise. Some, of course, require much more than this and some appear to do very well on considerably less. These latter cases are valuable as showing on how little food some people can subsist but they must not be accepted as criteria for the many. Individuals of this class are evidently endowed with very efficient powers of digestion and in addition probably belong to the anabolic temperament, and, as would be expected, most of them are past middle life when metabolic activity tends to slacken and the food required is an ever-diminishing quantity. The miller of Billericay is said to have lived in vigorous health for upwards of 18 years on a daily allowance of 16 ounces of flour made into a pudding with water, and the celebrated Cornaro, who lived to be nearly 100 years old, limited his diet to 12 ounces daily (made up of yelk of egg, soup, meat, and bread) together with 14 ounces of wine. I have myself met with cases in which the daily diet has been no more than this. Thus a lady, aged about 50 years, has lived for years on a diet somewhat as follows: breakfast and tea, two thin slices of bread-and-butter and a cupful of tea; midday meal, a small plateful of meat and vegetables, a small helping of pudding, a small piece of bread, and a glassful of ale. This lady would probably enjoy more vigorous health if she ate more but she declares that this diet is all-sufficing. The following is the diet of a plump and cheery old woman aged 84 years; breakfast, two thin slices of brown bread-and-butter, and one cupful of tea; dinner, a thin slice of bacon and three or four potatoes; tea, two slices of thin bread-and-butter and a cupful of tea; and supper, a slice of bread about one-third of an inch thick and a piece of cheese of "about the size of a penny." She has always, she says, been a small eater and people often tell her that she does not eat enough "to keep her going," but the food she takes satisfies her and she never feels any craving. The most remarkably young old man whom I have ever met consumes every day about four ounces of bread, three ounces of bacon, two ounces of meat, two ounces of sugar, one ounce of butter, and half a pint of ale. He lives in London and his food and beer cost him about 8*d.* a day. Dr. Keith, who is so well known for his forcible advocacy of slender rations both in health and disease, has for breakfast two or three ounces of bread, a quarter of an ounce each of butter and preserve, and half an ounce of fish or a quarter of an ounce of bacon; for lunch a cupful of cocoa or chocolate or a small tumblerful of milk, two or three ounces of bread, and about a quarter of an ounce each of butter and preserve; at 4 P.M. a small cupful of tea and sometimes biscuit or cake; at 7 P.M. soup and three ounces of white fish with a potato and another vegetable (if no fish, one or two ounces of lamb, game, rabbit, or tripe, but often neither fish nor flesh), a fair helping of some sweet or, instead of the latter, celery, cheese, oatcake, and butter. "On this diet," writes Dr. Keith, "I enjoy the best of health, and for my age (78 years) am up for a fair amount of exercise, walking three to six miles daily in good and sometimes in bad weather, and usually part of this is up a steep road with a rise of 250 feet. . ... I never feel what can be called hunger, and have not done so for many years. I could omit a meal at any time without discomfort. This I have long looked upon as the best proof of a perfect digestion." Mr. van Someren[1] finds that he can maintain good health on a very small quantity of food and he has brought forward evidence to show that by thoroughly masticating and insalivating the food nutrition can be maintained on a smaller quantity than when mastication is imperfect. This one can well believe, for efficient mastication facilitates digestion and the more perfect the digestion the more economically are the nutritive ingredients dealt with by the organism. Other things being equal, the more perfect the digestion the less is the quantity of food needed; and, indeed, as Dr. Keith observes, when digestion is perfect a meal can at any time be omitted without discomfort. This helps to explain how it is that one can educate oneself to subsist on smaller and smaller quantities of food. If a person who has been accustomed to eat an excess of food suddenly diminishes his daily allowance he may complain that he is being starved, that he feels "faint for food," and that he needs more food "to support him." His entire organism, but especially his digestive system, has become so accustomed to a copious diet that it cannot quickly adapt itself to the sudden curtailment. Above all he misses the mechanical stimulus of a large mass in his alimentary tract, just as he misses the chemical stimulus of the food; the morbid craving for food which the excessive eater is so wont to suffer from is indeed rather a craving for this mechanical and chemical stimulus than for nutriment and is exactly analogous to the drunkard's morbid craving for alcohol and to that of the opium-eater for opium. But by education the excessive eater can overcome this craving and his system can acquire such habits of economy as to make comparatively little go quite as far as a superabundance. This economical disposal of food is doubtless chiefly effected by the digestive organs, though it does not seem improbable that the tissues generally may be educated into thrifty habits.

How to reduce a sufficient diet to the minimum.—The quantity of food constituting a sufficient diet varies, of course, with circumstances. Now there are occasions when it is necessary to reduce the dietetic requirements of the body to a minimum, as, for instance, in grave affections of the heart, the lungs, or the kidneys, when it is desirable to give the failing organs as little work to do as possible. For this purpose the physician seeks to obtain the completest possible quiescence of the muscle system and to reduce the loss of heat to a minimum. He keeps the patient in bed, tells him to lie quiet and to relax his muscles to the utmost; he maintains a warm temperature in the room, gives all food and drink warm, and covers the entire body, save the head, with some light, non-conducting material; it is necessary that it should be light so that it may not impose unnecessary work upon the respiratory muscles. Old age, the female sex, and a sluggish metabolic habit are most favourable for the reduction of diet.

An Insufficient Diet.

Evils resulting from an insufficient diet.—The evil results of an insufficient diet—and here I refer essentially to an all-round insufficiency of proteids, fats, and saccharides—are too well known to need more than a passing notice. They are emaciation, anæmia, indigestion, nervous prostration, and mental depression, with lowered vitality generally and diminished resistance to disease. It is well, by the way, to observe that the requirements of nutrition are not necessarily satisfied by an abundant daily supply of food; that supply needs to be properly distributed in time, otherwise there may be temporary starvation, for though the organism is capable of storing food so that it can draw upon it in time of need, the capacity for so doing is, except in the case of fat and that in certain individuals only, very limited. Most of the energy expended by the organism is, in fact, derived from the food recently taken and it is therefore desirable that the intervals between meals should not be too long. This precaution is above all needful in the case of proteids which admit of only a very limited storage, being rapidly katabolised and eliminated as urea and allied bodies. Suppose, for instance, that the bulk of the daily proteid is consumed at the late meal, say at 7.30 or 8 P.M., a large part of it is katabolised and run out of the body before the next day is reached, as shown by the rapid rise in the output of urea shortly after the meal; there is thus a deficiency of circulating proteid to start the next day with, and hence care must be taken that a fresh supply is obtained at breakfast and midday. The amount can then be reduced at the late meal and nutrition can be maintained on a smaller amount than is otherwise possible. It is somewhat remarkable, in view of the comparatively small storage power which the animal organism has for proteids, that the carnivora should subsist for the most part on one meal in the 24 hours.

Ability of the organism to withstand starvation.—But while recognising the limit beyond which insufficient diet becomes starvation the physician should ever bear in mind that life can be sustained for a considerable time without any food whatsoever—especially after maturity is reached—if only the individual is well nourished to begin with. The public have a great idea of "keeping up the patient's strength" and believe that the most effectual way of doing this is to cram as much food as possible down his throat. They fail to realise that a person, especially if kept warm and quiet in bed, can go on living for a considerable time absolutely without food and that this period can be greatly lengthened by giving very small quantities daily. One constantly sees patients living quite comfortably on nutrient enemata alone and although it must not be too readily assumed that such patients are being completely nourished—for they may, as Hutchison observes, be living to a large extent upon their own tissues—the fact remains that life may be sustained for quite a long time on a very small amount of nutriment. It is, in sooth, no easy matter to kill a patient by starvation. I have in mind the case of a middle-aged man who lived for three months on a pint of milk a day and that while he was up and about. It is well to keep this fact in mind when there are urgent reasons for curtailing the diet or, it may be, for withholding it altogether for a time. I sometimes smile at the alarm expressed both by the patient and his friends when I tell some overfed, elderly sufferer from bronchitis who is being suffocated by a superfluity of fat that he could live for some days—and that with advantage—without any food at all. Such patients do not die from starvation. How many do!

---

[1] THE LANCET, August 10th, 1901, p. 389.

How long life can be sustained without food has been shown by the experience of professional fasters. Death from starvation does not generally occur until the body has lost one-third of its original weight—until, e.g., a 12-stone individual has been reduced to eight stones.

THE REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1900.[1]

First Notice.

We gladly welcome the appearance of these annual reports, for they are ably drawn up and not only embody much interesting information in regard to the diseases prevalent in India but they also afford a learned and excellent summary of the progress of medical research in Europe and other countries outside India in respect of those diseases which are more or less incidental to all climates alike. For this purpose the medical literature of all countries is laid under contribution and material which happens to be illustrative of any subject under consideration is drawn from various sources. The present report is of reduced size as compared with its predecessors, but it does not seem to us that this reduction has been attended with any sacrifice in the value of its contents. The report is signed by Surgeon-General Franklin, I.M.S., the newly-appointed Sanitary Commissioner with the Government of India, but it was written during, and refers to, a period prior to his assumption of office and the proofs were passed by the late Surgeon-General R. Harvey, C.B., D.S.O., his predecessor in that post. After a very brief summary of the meteorological phenomena of the year the different sections of the report, which as will be seen embrace a wide range, follow the usual order and are devoted to such subjects as the following: the European army in India, the native army, the jails of India, vital statistics of the general population with a history of the chief diseases, a general history of vaccination, sanitary works, and in conclusion there is a section in which a number of interesting and valuable points of information are grouped together under the heading of "General Remarks." The appendices to the report consist of various statistical tables and figures which, while they have little or no interest for the general reader, are nevertheless of value and importance to the medical statistician and to such as are bent upon making any special inquiry as to the prevalence of any given disease. Speaking generally we may say that the medical statistics for the British troops serving in India may be taken as being trustworthy, as well as may those perhaps for the native army and jail population. But this cannot be said of the figures relating to the native population. The mere registration of births and deaths is most defective and the results are untrustworthy and can be taken only as approximative at best. Still more is this the case as regards the nature of the diseases of which the native populations of India die, about which we really know but little.

To begin with the European army of India, we find that its health was better in 1900 than in the previous year as regards the amount of sickness, but the decrease in this respect was somewhat outweighed by an increase in mortality and invaliding. While the chief causes of admission were ague and venereal disease the chief causes of death were enteric fever and then hepatic abscess and cholera and the chief causes of invaliding venereal diseases, malarial fevers, cardiac affections, and pulmonary tubercle. Ague and venereal diseases caused respectively 27 and 26 per cent. of the total sickness. Enteric fever caused 33 per cent. of the total deaths, hepatic abscess 11 per cent., and cholera 10 per cent. It may be mentioned that the chief causes of admission in the China Field Force were ague, dysentery, venereal disease, and diarrhœa, and that the main causes of death were enteric fever and dysentery.

According to the report Madras was the most unhealthy of the four commands, Bombay coming next, and both being more unhealthy than in 1899. Bengal had the highest mortality from tubercle of the lungs, dysentery, and abscess of the liver; the Punjab from remittent fever, heat-stroke, and pneumonia; Madras from cholera, ague, and dysentery; and Bombay from small-pox, enteric fever, and diarrhœa. Passing over in the meantime such diseases as influenza and cholera we come to ague which gave rise, as we have said, to nearly 27 per cent. of the admissions from all causes. The greatest outbreaks were those at Ferozepore and at Fort Dufferin, Mandalay. At Ferozepore, we are told, the increase of the disease—much of it of a severe and grave type—became explosively sudden in October. At the same time mosquitoes (anopheles) were found to be unusually abundant and troublesome in barracks, bungalows, and hospitals. The women, children, and bandsmen returning from the hills were all attacked and from their cases it was judged that the incubation period of the disease is about 14 days. The whole wing of the Oxford Light Infantry being completely prostrated and incapacitated for duty the men were sent to Kurrachee. Other classes of the population also suffered. At Mandalay the men of the 2nd Durham Light Infantry stationed at Fort Dufferin suffered severely, while the artillery near Mandalay Hill were practically free. It is not at all satisfactory to be told that the infantry barracks are situated in a marsh and that the locality is so notoriously unhealthy that it was in King Theobaw's time abandoned by the Burmese. About 350 men of the corps were sent away to healthy stations and ultimately the whole regiment was removed to Wellington.

Following these statements regarding fever of an undoubted malarial nature and some remarks recording the finding of anopheles at numerous stations, the report, in continuation of a subject which is being carried on from year to year, enters upon a consideration of the nature and causation of various other forms of fever which occupy a prominent place in the nomenclature of disease used in the army medical returns of India. We allude to such diseases as remittent fever, simple continued fever, and enteric fever. There exists, no doubt, much diversity of opinion in regard to the exact nature and pathology of the fevers which prevail, or are alleged to prevail, in India and their differentiation from one another. As regards enteric fever, for example, modern views and researches in respect of its bacillary origin, the discovery and application of new tests—Widal's reaction for instance—and a more enlarged field of view, embracing a number of cases such as some years ago would not probably have been included as even coming within the category of enteric fever, have given quite a new standpoint from which to study this form of fever. The report of the Sanitary Commissioner for the year 1900 opens up some fresh and notable points for consideration in this matter, the discussion of which must for the present moment be deferred. The question of the liability of the native population to enteric fever, for example, is calculated to throw a new light on the spread of this disease in India. It will now, however, suffice to say that there was again a great decrease of both morbidity and mortality from enteric fever among the European troops. The admission-rate was the lowest that has been since that of 1888. Of the causes of decrease probably the most powerful were the almost complete absence of drafts from England and the freedom from field service, but the reduction is not so great as might have been expected had the prevalence of the disease been entirely due to the supply of fresh susceptible subjects. It is stated that statistical evidence shows that of late years men of higher ages and of longer periods of service have been attacked in higher proportion to their strength than formerly. Still, the report for 1900 shows, in accordance with all past experience, that the greatest liability in Europeans to suffer and to die from enteric fever is between the ages of 20 and 25 and in the first three years of Indian service. The months of its maximum prevalence for India as a whole are May, April, and August, but this maximum period differs in northern and in peninsular India.

---

[1] Annual Report of the Sanitary Commissioner with the Government of India, 1900, with Appendices and Returns of Sickness and Mortality among European Troops, Native Troops, and Prisoners in India for the year. Calcutta: Office of the Superintendent of Government Printing, India. 1902. Price 3 rupees.

With regard to dysentery, diarrhœa, and hepatic abscess the conclusions set forth on pages 23 and 24 of the report are very much in accordance with those recorded in previous reports and are well worth reading. It is worthy of note that the mortality from abscess of the liver in 1900 was 31 times greater among European than among native soldiers, notwithstanding that the admission ratio from dysentery among European soldiers was to the ratio of the native soldiers as 1 : 1·95.

Touching the lamentable prevalence of venereal diseases among British troops serving in India, which a few years ago forced itself upon public attention, we are glad to notice that the year 1900 shows a decrease. The admission-rate for India for that year was 298·1 per 1000, as against 313·4 in the previous year and 362·9 in 1898. In other words there were 15 fewer admissions to hospital per 1000 for these diseases in 1900 than in 1899. This is satisfactory as far as it goes but it is not a striking decrease. The causes assigned for it are detailed on page 25 of the report but we need not enter into these. Although we gladly hail every attempt that is made to increase the moral tone and self-control of the soldier we nevertheless fear that these measures alone will prove inadequate and illusory and while we fully recognise all the difficulties which the subject involves we think that the evil can only be effectively dealt with by sanitary legislation of some kind.

THE METROPOLITAN WATER-SUPPLY: THE LONDON WATER BILL.

THE Joint Committee of the two Houses of Parliament appointed to report on the London Water Bill sat on May 12th, 13th, 14th, and 15th, and then adjourned until Tuesday, May 27th. The course of the proceedings has not been altogether a smooth one, and the greater the amount of time spent in considering the effects of the Bill the greater the number of the difficulties which become apparent. The space at our disposal will admit of nothing more than a general view of the proceedings of the Committee. The fact that in regard to essential parts of the Bill the most divergent views are held by members of the Committee is evident.

At the sitting of May 13th Lord BALFOUR of BURLEIGH explained fully the effects of the decision of the Committee in regard to the schedule which it had once decided to delete. This schedule is to be reconsidered line by line. When this is done if a question be put that such-and-such a line be deleted and the Committee does not agree unanimously, and if the members then vote on the question and there be an equality of votes, then according to the rule which presumes that an equality of votes means a negative the line will not be deleted. If, however, the amendment were put the other way—that is, to insert words, the rule would tell in exactly the opposite direction and an equality of votes would tell against the resolution. It was ingeniously suggested by Mr. BALFOUR BROWN that it might be competent for any member of the Committee to move that the resolution of May 12th should stand and that if there were an equality of votes on that motion the resolution of May 12th would go. Lord BALFOUR of BURLEIGH, however, said that as chairman he should probably rule that the proper course would be to move to delete a certain passage in the Bill. The position of chairman to a Joint Committee of the two Houses of Parliament evidently gives opportunities for a little *finesse*.

The sitting of May 14th was occupied chiefly in considering Clause 2 of the Bill. This clause provided that from an "appointed day" the Water Board should hold the undertaking of each metropolitan water company, exercise all the rights, &c., of the company, and be subject to all the duties and obligations of the company. On behalf of the water companies an amendment was introduced with the object of securing that some date should be fixed by the court of arbitration anterior to the commencement of the arbitration, and from which date any undertaking when it was transferred should vest in the Water Board as "a going concern."

Counsel for the Local Government Board objected to the words "a going concern," which seems popularly to indicate the propriety of some extra payment on the part of a purchaser. This, indeed, was practically admitted by Mr. DANCKWERTS, one of the counsel for the water companies, who said that the words were introduced into Tramway Bills, where there is a transference of these undertakings, and it was desired to get rid of the Shaw-Lefevre clause which was, he explained, the "old-iron" clause. The amendment was lost by seven to three.

On Sub-section 2 of Clause 2 amendments were moved by the water companies and by the London County Council. This sub-section provided that the Water Board should issue to each company in consideration for the undertaking so transferred such an amount of water stock created under this Act as may be agreed upon between the board and the company, or in default of agreement as may be determined by arbitration under the Act. The London County Council opposed this sub-section on two points. In the first place a newly constituted Water Board should, they argued, be prevented from coming to an immediate agreement as to the price to be paid for a water company's undertaking—the matter of price should in all cases be referred to arbitration. Briefly, the new Water Board was not to be trusted to act for the best in the interests of those whom it represented. The second point was that power should be given for the companies to be paid in cash.

On behalf of the water companies Mr. PEMBER, K.C., suggested that the words "as compensation for" should be used instead of the words "in consideration for,"

On behalf of the Local Government Board Mr. J. D. FITZGERALD, K.C., pointed out the advantages which Mr. Banbury had at a previous sitting clearly shown were likely to follow the method of payment by water stock instead of payment in cash.

The committee accepted the alteration suggested by Mr. Pember and further decided that payment for the undertakings should be made in cash. The sub-section was therefore amended as follows:—

> 1. Subject to the provisions of this Act as from the appointed day the undertaking of each of the metropolitan water companies shall be transferred to and shall vest in the Water Board, and there shall also be transferred from the company to the Water Board all liabilities with repect to any debenture stock or mortgage debt of the company and all other debts, liabilities, and obligations of the company then existing. 2. The Water Board shall pay to each company as compensation for the transfer of the undertaking such sum as may be agreed on between the Board and the company, or in default of agreement as may be determined by arbitration under this Act, but the sum so payable may, if the Water Board and the company so agree, be discharged wholly or partly in water stock; an agreement for the purposes of this section shall not be made except in pursuance of a resolution of an absolute majority of the whole number of the Water Board after 10 clear days' notice in writing of the meeting and of the intention to propose the resolution has been given to every member of the board.

The Committee decided that Ilford and Barking should not be dealt with in the Bill.

Clause 8 gave rise to a good deal of discussion. As originally drawn it dealt with supply in bulk to certain districts and persons. The places mentioned were Croydon and Richmond and the urban districts of Cheshunt, Enfield, Tottenham, and Ware, and the clause provided also for the supply by the council of any rural district situate wholly or partly within the limits of supply on conditions to be arranged between the Water Board and these authorities, or in case of disagreement on terms to be decided by arbitration. On behalf of the London County Council its statistical officer gave it as his opinion that these areas should either be definitely put outside the water area or should remain within it. No option in the matter should be given to the local authorities in the manner provided by the Bill.

In answer to Lord BALFOUR OF BURLEIGH counsel employed by the London County Council admitted that that council was not authorised to represent the rural districts in this matter.

Counsel for the Hertfordshire Council Council and for the rural districts of Essex said that these authorities were in favour of the Bill as it stood, and the Committee decided generally in favour of the clause after some amendments had been made.

Clause 9 deals with a financial matter—the substitution of water stock for irredeemable debenture stock.

Mr. BAGGALLAY, on behalf of the water companies, explained that it might be of advantage to the Committee to know that the question as presented was really a sort of triangular duel in which the three belligerents were the Local Government Board, the London County Council, and the water companies.

The committee decided that the clause should stand.

Towards the end of the sitting Mr. PEMBER, K.C., on behalf of two water company directors who were also Members of Parliament, said that they were aggrieved that counsel for the Local Government Board had, as he stated, said that the water companies were in league with the London County Council to wreck the Bill.

Lord BALFOUR of BURLEIGH asked whether the London County Council and the water companies were keenly desirous that the Bill should pass. Mr. PEMBER could not say that the companies were keenly desirous that the Bill should pass; they wished to assist the Committee to so amend it that it might become a just Bill (which being interpreted means that they should obtain a pecuniary compensation of large amount).

At the sitting of May 15th Mr. FITZGERALD, K.C., took exception to the strictures of Mr. Pember and stated that he had said that although the interests of the water companies and of the London County Council did not always agree they were agreed that this Bill should not become law. That was the inference he had drawn; the inference was, he was now told, incorrect. He therefore withdrew and would proceed on the assumption that both the water companies and the London County Council wished that the Bill should become law.

Lord BALFOUR of BURLEIGH said that they would take it that these two bodies desired to assist in improving the Bill.

The Committee then proceeded to consider the financial provisions proposed in regard to the expenses of the Water Board and Mr. BLENNERHASSETT, K.C., on behalf of the City of Westminster, proposed a clause providing that before any charge fell on the rates the Water Board should exercise to the full the powers of charging at present enjoyed by the companies whose undertakings were to be transferred to the Board. This clause, subject to some amendment, was accepted.

Clause 12, which deals with powers of borrowing by the Water Board, was agreed to.

Clause 13, which relates to the issue of water stock, was not fully discussed and a decision in regard to it was deferred.

Clause 14 (which makes provision as to discharge of loans), Clause 15 (which deals with accounts and audit), Clause 16 (which provides as to the borrowing power of certain local authorities), and Clause 17 (which deals with the application of capital receipts) were agreed to.

ANNUAL GENERAL MEETING OF THE MEDICAL DEFENCE UNION.

THE annual general meeting of the Medical Defence Union was held on May 15th at the registered offices of the union at 4, Trafalgar-square, London, under the presidency of Mr. M. A. MESSITER.
